Hybrid Systems
Approximation of reachable state sets

Hybrid Systems: Computation and Control, LNCS 2623, pp. 482-497, 2003
We had a look at state set approximations by
- convex polyhedra,
and at the basic operations
- testing for membership,
- intersection, and
- union
on these.
Thus we can
- approximate state sets and
- compute with them.

How is all this used in the reachability analysis procedure?
General reachability procedure

**Input:** Set \( \text{Init} \) of initial states.

**Algorithm:**

\[
R^{\text{new}} := \text{Init}; \\
R := \emptyset; \\
\text{while } (R^{\text{new}} \neq \emptyset) \{ \\
\quad R := R \cup R^{\text{new}}; \\
\quad R^{\text{new}} := \text{Reach}(R^{\text{new}}) \setminus R; \\
\}\]

**Output:** Set \( R \) of reachable states.

---

What is “Reach”?
What is “Reach”?

For hybrid systems, independently of the exact definition of “Reach”, it will involve the following computations:

Given a state set $R$, compute

- the set of states reachable from $R$ by a flow (i.e., time transition), and
- the set of states reachable from $R$ by a jump (i.e., discrete transition).

Computing the jump successors, i.e., the flow pipe, of a set can be done with the operations we already introduced.

The harder part is computing the flow successors. So let’s start with that...
Approximating a flow pipe

Consider a dynamical system with state equation

\[ \dot{x} = f(x(t)). \]

We assume \( f \) to be Lipschitz continuous so that for every initial state \( x_0 \) there is a unique solution \( x(t, x_0) \) to the state equation.
Approximating a flow pipe

Consider a dynamical system with state equation

$$\dot{x} = f(x(t)).$$

We assume $f$ to be Lipschitz continuous so that for every initial state $x_0$ there is a unique solution $x(t, x_0)$ to the state equation.

The set of reachable states at time $t$ from a set of initial states $X_0$ is defined as

$$\mathcal{R}_t(X_0) = \{ x_f \mid \exists x_0 \in X_0. \ x_f = x(t, x_0) \}.$$
Approximating a flow pipe

Consider a dynamical system with state equation

\[ \dot{x} = f(x(t)). \]

We assume \( f \) to be Lipschitz continuous so that for every initial state \( x_0 \) there is a unique solution \( x(t, x_0) \) to the state equation.

The set of reachable states at time \( t \) from a set of initial states \( X_0 \) is defined as

\[ \mathcal{R}_t(X_0) = \{ x_f \mid \exists x_0 \in X_0. x_f = x(t, x_0) \}. \]

The set of reachable states, the flow pipe, from \( X_0 \) in the time interval \([t_1, t_2]\) is defined as

\[ \mathcal{R}_{[t_1, t_2]}(X_0) = \bigcup_{t \in [t_1, t_2]} \mathcal{R}_t(X_0). \]
Consider a dynamical system with state equation

\[ \dot{x} = f(x(t)). \]

We assume \( f \) to be Lipschitz continuous so that for every initial state \( x_0 \) there is a unique solution \( x(t, x_0) \) to the state equation.

The set of reachable states at time \( t \) from a set of initial states \( X_0 \) is defined as

\[ R_t(X_0) = \{ x_f | \exists x_0 \in X_0. x_f = x(t, x_0) \}. \]

The set of reachable states, the flow pipe, from \( X_0 \) in the time interval \([t_1, t_2]\) is defined as

\[ R_{[t_1, t_2]}(X_0) = \bigcup_{t \in [t_1, t_2]} R_t(X_0). \]

We describe a solution which approximates the flow pipe by a sequence of convex polytopes.
Definition (Convex polytope)

Let $POLY(C, d)$ denote the convex polytope defined by the pair $(C, d) \in \mathbb{R}^{m \times n} \times \mathbb{R}^m$ according to

$$POLY(C, d) = \{ x | Cx \leq d \}.$$
Definition (Convex polytope)

Let $POLY(C, d)$ denote the convex polytope defined by the pair $(C, d) \in \mathbb{R}^{m \times n} \times \mathbb{R}^m$ according to

$$POLY(C, d) = \{x \mid Cx \leq d\}.$$ 

- Each row of $C$ is the normal vector to the $i$th face of the polytope.
Definition (Convex polytope)

Let $POLY(C,d)$ denote the convex polytope defined by the pair $(C,d) \in \mathbb{R}^{m \times n} \times \mathbb{R}^m$ according to

$$POLY(C,d) = \{x \mid Cx \leq d\}.$$ 

- Each row of $C$ is the normal vector to the $i$th face of the polytope.
- A polytope $P$ has a finite number of vertices $V(P)$, which are points in $P$ that cannot be written as a strict convex combination of any other two points in $P$. 

Definition (Convex polytope)

Let $POLY(C, d)$ denote the convex polytope defined by the pair $(C, d) \in \mathbb{R}^{m \times n} \times \mathbb{R}^m$ according to

$$POLY(C, d) = \{x \mid Cx \leq d\}.$$ 

- Each row of $C$ is the normal vector to the $i$th face of the polytope.
- A polytope $P$ has a finite number of vertices $V(P)$, which are points in $P$ that cannot be written as a strict convex combination of any other two points in $P$.
- Given a finite set of points $\Gamma$, the convex hull $CH(\Gamma)$ of $\Gamma$ is the smallest convex set that contains $\Gamma$. 
Problem statement for polyhedral approximation of flow pipes

Given

- a set \( X_0 \) of initial states which is a polytope, and
- a final time \( t_f \),

compute a polyhedral approximation \( \hat{R}_{[0,t_f]}(X_0) \) to the flow pipe \( R_{[0,t_f]}(X_0) \) such that

\[
R_{[0,t_f]}(X_0) \subseteq \hat{R}_{[0,t_f]}(X_0).
\]
Flow pipe segmentation

Since a single convex polyhedra would strongly overapproximate the flow pipe, we compute a sequence of convex polyhedra, each approximating a flow pipe segment.
Segmented flow pipe approximation

Let the time interval $[0, t_f]$ be divided into $0 < N \in \mathbb{N}$ time segments

$$[0, t_1], [t_1, t_2], \ldots, [t_{N-1}, t_f]$$

with $t_i = i \cdot \frac{t_f}{N}$.
Segmented flow pipe approximation

Let the time interval $[0, t_f]$ be divided into $0 < N \in \mathbb{N}$ time segments

$$[0, t_1], [t_1, t_2], \ldots, [t_{N-1}, t_f]$$

with $t_i = i \cdot \frac{t_f}{N}$.

We generate an approximation $\hat{R}_{[t_1, t_2]}(X_0)$ for each flow pipe segment:

$$R_{[t_1, t_2]}(X_0) \subseteq \hat{R}_{[t_1, t_2]}(X_0).$$
Segmented flow pipe approximation

Let the time interval $[0, t_f]$ be divided into $0 < N \in \mathbb{N}$ time segments

$$[0, t_1], [t_1, t_2], \ldots, [t_{N-1}, t_f]$$

with $t_i = i \cdot \frac{t_f}{N}$.

We generate an approximation $\hat{\mathcal{R}}_{[t_1,t_2]}(X_0)$ for each flow pipe segment:

$$\mathcal{R}_{[t_1,t_2]}(X_0) \subseteq \hat{\mathcal{R}}_{[t_1,t_2]}(X_0).$$

The complete flow pipe approximation is the union of the approximation of all $N$ pipe segments:

$$\mathcal{R}_{[0,t_f]}(X_0) \subseteq \hat{\mathcal{R}}_{[0,t_f]}(X_0) = \bigcup_{k=1,\ldots,N} \hat{\mathcal{R}}_{[t_{k-1},t_k]}(X_0)$$
Approximation of a flow pipe segment

The approximation of the flow pipe for the time segment \([t_{k-1}, t_k]\) \((k \in \{1, \ldots, N\})\) consists of the following steps:
Approximation of a flow pipe segment

The approximation of the flow pipe for the time segment \([t_{k-1}, t_k]\) \((k \in \{1, \ldots, N\})\) consists of the following steps:

- **Evolve vertices**: Compute the set of points reachable from the vertices of \(X_0\) in time \(t_{i-1}\) and in time \(t_i\).

\[ V_{t_{k-1}}(X_0) \]

\[ V_{t_k}(X_0) \]
The approximation of the flow pipe for the time segment \([t_{k-1}, t_k]\) (\(k \in \{1, \ldots, N\}\)) consists of the following steps:

- **Evolve vertices**: Compute the set of points reachable from the vertices of \(X_0\) in time \(t_{i-1}\) and in time \(t_i\).
- **Determine hull**: Compute the convex hull of those points.
Approximation of a flow pipe segment

The approximation of the flow pipe for the time segment $[t_{k-1}, t_k]$ ($k \in \{1, \ldots, N\}$) consists of the following steps:

- **Evolve vertices**: Compute the set of points reachable from the vertices of $X_0$ in time $t_{i-1}$ and in time $t_i$.
- **Determine hull**: Compute the convex hull of those points.
- **Bloat hull**: Enlarge the hull until it contains all points of the flow pipe segment.
1. Evolve vertices

To gain some geometrical information about the flow pipe segment, we begin with taking sample points at times $t_{k-1}$ and $t_k$ from the trajectories emanating from the vertices of $X_0$. 
1. Evolve vertices

To gain some geometrical information about the flow pipe segment, we begin with taking sample points at times $t_{k-1}$ and $t_k$ from the trajectories emanating from the vertices of $X_0$.

In particular, we compute the sets $V_{t_{k-1}}(X_0)$ and $V_{t_k}(X_0)$ where

$$V_t(X_0) = \{ x(t, v) \mid v \in V(X_0) \}.$$
1. Evolve vertices

To gain some geometrical information about the flow pipe segment, we begin with taking sample points at times $t_{k-1}$ and $t_k$ from the trajectories emanating from the vertices of $X_0$.

In particular, we compute the sets $V_{t_{k-1}}(X_0)$ and $V_{t_k}(X_0)$ where

$$V_t(X_0) = \{x(t, v) \mid v \in V(X_0)\}.$$ 

Each point in the above sets can be obtained
- by analytic solution of the state equation and computing the value, or
- by simulation.
2. Determine hull

We use the evolved vertices in $V_{t_{k-1}}(X_0)$ and $V_{t_k}(X_0)$ to form a convex hull which serves as an initial approximation to the flow pipe segment $\mathcal{R}_{[t_{k-1}, t_k]}(X_0)$, denoted by

$$\Phi_{[t_{k-1}, t_k]}(X_0) = CH(V_{t_{k-1}}(X_0) \cup V_{t_k}(X_0)).$$
2. Determine hull

We use the evolved vertices in $V_{t_{k-1}}(X_0)$ and $V_{t_k}(X_0)$ to form a convex hull which serves as an initial approximation to the flow pipe segment $R_{[t_{k-1}, t_k]}(X_0)$, denoted by

$$
\Phi_{[t_{k-1}, t_k]}(X_0) = CH(V_{t_{k-1}}(X_0) \cup V_{t_k}(X_0)).
$$

Note that $\Phi_{[t_{k-1}, t_k]}(X_0)$ may not contain the whole flow pipe segment $R_{[t_{k-1}, t_k]}(X_0)$. 

We use the evolved vertices in $V_{t_k-1}(X_0)$ and $V_{t_k}(X_0)$ to form a convex hull which serves as an initial approximation to the flow pipe segment $\mathcal{R}_{[t_{k-1}, t_k]}(X_0)$, denoted by

$$\Phi_{[t_{k-1}, t_k]}(X_0) = CH(V_{t_{k-1}}(X_0) \cup V_{t_k}(X_0)).$$

Note that $\Phi_{[t_{k-1}, t_k]}(X_0)$ may not contain the whole flow pipe segment $\mathcal{R}_{[t_{k-1}, t_k]}(X_0)$.

Let $(C_\Phi, d_\Phi)$ be the matrix-vector pair defining the convex hull, i.e.,

$$\Phi_{[t_{k-1}, t_k]}(X_0) = POLY(C_\Phi, d_\Phi).$$
The normal vector on each face of the polytope points outward.
3. Bloat hull

- The normal vector on each face of the polytope points outward.
- We use the normal vectors to the faces of this convex hull as a set of direction vectors to bloat the convex set until it contains the whole flow pipe segment.
3. Bloat hull

- The normal vector on each face of the polytope points outward.
- We use the normal vectors to the faces of this convex hull as a set of direction vectors to **bloat the convex set** until it contains the whole flow pipe segment.
- Given: $POLY(C_\Phi, d_\Phi)$. 
The normal vector on each face of the polytope points outward.

We use the normal vectors to the faces of this convex hull as a set of direction vectors to \textit{bloat the convex set} until it contains the whole flow pipe segment.

Given: \( POLY(C_\Phi, d_\Phi) \).

We want: \( \mathcal{R}_{[t_{k-1}, t_k]}(X_0) \subseteq POLY(C_\Phi, \boxed{d}) \).
3. Bloat hull

- We compute $d$ as the solution to the following optimization problem:

$$\min_d \text{volume}\left[\text{POLY}(C_\Phi, d)\right]$$

s.t. $\mathcal{R}[t_{k-1}, t_k](X_0) \subseteq \text{POLY}(C_\Phi, d)$.
3. Bloat hull

- We compute $d$ as the solution to the following optimization problem:

\[
\begin{align*}
\min_d & \quad \text{volume}[\text{POLY}(C_\Phi, d)] \\
\text{s.t.} & \quad \mathcal{R}[t_{k-1}, t_k](X_0) \subseteq \text{POLY}(C_\Phi, d).
\end{align*}
\] (1)

- The $i$th component $d^*_i$ of the optimum $d^*$ can be found by solving

\[
\begin{align*}
\max_x & \quad c^T_ix \\
\text{s.t.} & \quad x \in \mathcal{R}[t_{k-1}, t_k](X_0).
\end{align*}
\] (2)
3. Bloat hull

- We compute $d$ as the solution to the following optimization problem:

\[
\begin{align*}
\min_d & \quad \text{volume}[\text{POLY}(C\Phi, d)] \\
\text{s.t.} & \quad \mathcal{R}_{[t_{k-1}, t_k]}(X_0) \subseteq \text{POLY}(C\Phi, d).
\end{align*}
\] (1)

- The $i$th component $d^*_i$ of the optimum $d^*$ can be found by solving

\[
\max_x c_i^T x \quad \text{s.t.} \quad x \in \mathcal{R}_{[t_{k-1}, t_k]}(X_0).
\] (2)

- or, equivalently,

\[
\max_{x_0, t} c_i^T x(t, x_0) \quad \text{s.t.} \quad x_0 \in X_0, \ t \in [t_{k-1}, t_k].
\] (3)
3. Bloat hull

- We compute $d$ as the solution to the following optimization problem:

$$\min_d \quad \text{volume}[\text{POLY}(C_\Phi, d)] \quad \text{subject to} \quad R_{[t_{k-1}, t_k]}(X_0) \subseteq \text{POLY}(C_\Phi, d).$$

- The $i$th component $d^*_i$ of the optimum $d^*$ can be found by solving

$$\max_x c_i^T x \quad \text{subject to} \quad x \in R_{[t_{k-1}, t_k]}(X_0).$$

- or, equivalently,

$$\max_{x_0, t} c_i^T x(t, x_0) \quad \text{subject to} \quad x_0 \in X_0, \quad t \in [t_{k-1}, t_k].$$

- Solution $(x_0^*, t^*)$ to 3 $\rightarrow$

Solution $x(t^*, x_0^*)$ to 2 $\rightarrow$

Solution $d^*_i = c_i^T x(t^*, x_0^*)$ to 1.
Example

- **Van der Pol equation:**
  \[
  \begin{align*}
  \dot{x}_1 &= x_2 \\
  \dot{x}_2 &= -0.2(x_1^2 - 1)x_2 - x_1.
  \end{align*}
  \]

- **Initial set:** \(X_0 = \{(x_1, x_2) \mid 0.8 \leq x_1 \leq 1 \land x_2 = 0\}\).

- **Time:** \(t_f = 10\).

- **Segments:** 20
