Contents & Goals

Last Lecture:

- Networks of Timed Automata
- Uppaal Demo

This Lecture:

- **Educational Objectives:** Capabilities for following tasks/questions:
 - What are decidable problems of TA?
 - How can we show this? What are the essential premises of decidability?
 - What is a region? What is the region automaton of this TA?
 - What's the time abstract system of a TA? Why did we consider this?
 - What can you say about the complexity of Region-automaton based reachability analysis?
- **Content:**
 - **Timed Transition System of a network of timed automata**
 - Location Reachability Problem
 - Constructive, region-based decidability proof

The Location Reachability Problem

3/11

The Location Reachability Problem

Given: A timed automaton \mathcal{A} and one of its control locations ℓ_i .

Question: Is ℓ_i **reachable**?

That is, is there a transition sequence of the form

$$(t_{init}, 0) \xrightarrow{\lambda_1} (\ell_1, \nu_1) \xrightarrow{\lambda_2} (\ell_2, \nu_2) \xrightarrow{\lambda_3} \dots \xrightarrow{\lambda_n} (\ell_n, \nu_n) = (\ell_i, \nu)$$

in the labeled transition system $T(\mathcal{A})$?

- **Note:** Decidability is not **so** obvious, recall that
- clocks range over real numbers, thus infinitely many configurations,
- at each configuration, uncountably many transitions — may originate
- **Consequence:** The timed automata as we consider them here **cannot** encode a 2-counter machine, and they are strictly less expressive than DC.

4/11

Decidability of The Location Reachability Problem

Claim: (Theorem 4.33)

The location reachability problem is **decidable** for timed automata.

Approach: Constructive proof.

- Observe: clock constraints are **simple**
 - w.l.o.g. assume constants $c \in \mathbb{N}_0$.
- **Def. 4.19: time-abstract transition system** $\mathcal{L}(\mathcal{A})$ — abstracts from uncountably many delay transitions, still infinite-state.
 - **LEM. 4.20:** location reachability of \mathcal{A} is preserved in $\mathcal{L}(\mathcal{A})$.
 - **Def. 4.29: region automaton** $\mathcal{R}(\mathcal{A})$ — equivalent configurations collapse into regions
 - **LEM. 4.32:** location reachability of $\mathcal{L}(\mathcal{A})$ is preserved in $\mathcal{R}(\mathcal{A})$.
 - **LEM. 4.28:** $\mathcal{R}(\mathcal{A})$ is finite.

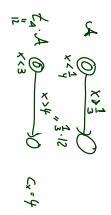

5/11

Without Loss of Generality: Natural Constants

Recall: Simple clock constraints are $\varphi ::= x \sim c \mid |x - y| \sim c \mid \varphi \wedge \psi$ with $x, y \in X, c \in \mathbb{Q}_0^+$, and $\sim \in \{<, >, \leq, \geq\}$.

- Let $C(\mathcal{A}) = \{c \in \mathbb{Q}_0^+ \mid c \text{ appears in } \mathcal{A}\}$ — $C(\mathcal{A})$ is finite! (Why?)
- Let \mathcal{L}_A be the **least common multiple** of the denominators in $C(\mathcal{A})$.
- Let $\mathcal{L}_{\mathcal{A}, \mathcal{A}}$ be the TA obtained from \mathcal{A} by **multiplying** all constants by \mathcal{L}_A .

6/11

Recall: Simple clock constraints are $\varphi ::= x \sim c \mid x - y \sim c \mid \varphi \wedge \varphi$ with $x, y \in X, c \in \mathbb{Q}_0^+$, and $\sim \in \{<, >, \leq, \geq\}$.

- Let $C(\mathcal{A}) = \{c \in \mathbb{Q}_0^+ \mid c \text{ appears in } \mathcal{A}\}$ — $C(\mathcal{A})$ is finite (Why?)
- Let $L_{\mathcal{A}}$ be the **least common multiple** of the denominators in $C(\mathcal{A})$.
- Let \mathcal{A}' be the TA obtained from \mathcal{A} by **multiplying** all constants by $L_{\mathcal{A}}$.
- Then:
 - $C(\mathcal{A}', \mathcal{A}) \subset \mathbb{N}_0$
 - A location l is reachable in $\mathcal{A}', \mathcal{A}$ if and only if l is reachable in \mathcal{A} .
 - That is: we can **without loss of generality** in the following consider only timed automata \mathcal{A} with $C(\mathcal{A}) \subset \mathbb{N}_0$.

Definition. Let x be a clock of timed automaton \mathcal{A} (with $C(\mathcal{A}) \subset \mathbb{N}_0$). We denote by $c_x \in \mathbb{N}_0$ the **largest time constant** c that appears together with x in a constraint of \mathcal{A} .

Claim: (Theorem 4.33)

The location reachability problem is **decidable** for timed automata.

Approach: Constructive proof.

✓ Observe: clock constraints are **simple**

— w.l.o.g. assume constants $c \in \mathbb{N}_0$.

✗ **Def. 4.19:** **time-abstract transition system** $\mathcal{U}(\mathcal{A})$ — abstracts from uncountably many delay transitions, still infinitesate.

✗ **Len. 4.20:** location reachability of \mathcal{A} is preserved in $\mathcal{U}(\mathcal{A})$.

✗ **Def. 4.29:** **region automaton** $\mathcal{R}(\mathcal{A})$ — equivalent configurations collapse into regions

✗ **Len. 4.32:** location reachability of $\mathcal{U}(\mathcal{A})$ is preserved in $\mathcal{R}(\mathcal{A})$.

✗ **Len. 4.28:** $\mathcal{R}(\mathcal{A})$ is finite.

Recall: $\mathcal{T}(\mathcal{A}) = (Conf(\mathcal{A}), Time \cup B_{\mathcal{A}}, \{\stackrel{\lambda}{\rightarrow}\}_{\lambda \in Time \cup B_{\mathcal{A}}}, C_{\mathcal{A}})$

• Note: The $\stackrel{\lambda}{\rightarrow}$ are binary relations on configurations.

Definition. Let \mathcal{A} be a TA. For all $(l_1, \nu_1), (l_2, \nu_2) \in Conf(\mathcal{A})$,

if and only if there exists some $(l', \nu') \in Conf(\mathcal{A})$ such that

$$(l_1, \nu_1) \stackrel{\lambda_1}{\rightarrow} (l', \nu') \text{ and } (l', \nu') \stackrel{\lambda_2}{\rightarrow} (l_2, \nu_2).$$

Remark. The following property of time additivity holds

$$\forall l_1, l_2 \in Time: \stackrel{\lambda_1}{\rightarrow} \circ \stackrel{\lambda_2}{\rightarrow} = \stackrel{l_1+l_2}{\rightarrow}$$

Time-abstract Transition System

Definition 4.19. [Time-abstract transition system] Let \mathcal{A} be a timed automaton. The **time-abstract transition system** $\mathcal{U}(\mathcal{A})$ is obtained from $\mathcal{T}(\mathcal{A})$ (Def. 4.4) by taking

$$\mathcal{U}(\mathcal{A}) = (Conf(\mathcal{A}), B_{\mathcal{A}}, \{\stackrel{\alpha}{\rightarrow}\}_{\alpha \in B_{\mathcal{A}}}, C_{\mathcal{A}})$$

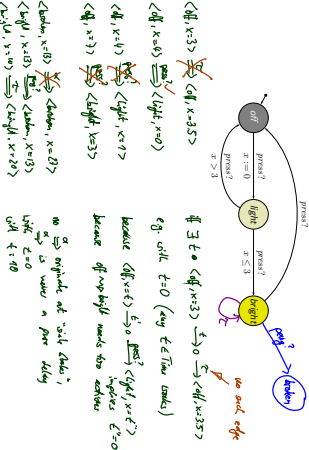

where

is defined as follows: Let $(l, \nu), (l', \nu') \in Conf(\mathcal{A})$ be configurations of \mathcal{A} and $\alpha \in B_{\mathcal{A}}$ an action. Then

$$(l, \nu) \stackrel{\alpha}{\rightarrow} (l', \nu') \text{ if and only if there exists } t \in Time \text{ such that } (l, \nu) \stackrel{\alpha}{\rightarrow} \circ \stackrel{t}{\rightarrow} (l', \nu').$$

Example

$$(l, \nu) \stackrel{\alpha}{\rightarrow} (l', \nu') \text{ iff } \exists t \in Time \bullet (l, \nu) \stackrel{\alpha}{\rightarrow} \circ \stackrel{t}{\rightarrow} (l', \nu')$$

Location Reachability is preserved in $\mathcal{U}(\mathcal{A})$

Lemma 4.20. For all locations l of a given timed automaton \mathcal{A} the following holds:
 l is reachable in $\mathcal{T}(\mathcal{A})$ if and only if l is reachable in $\mathcal{U}(\mathcal{A})$.

Proof:
 " \Leftarrow " only
 \Rightarrow " l reachable in $\mathcal{T}(\mathcal{A})$ "
 There is $\langle l, \nu \rangle \xrightarrow{\lambda_1} \dots \xrightarrow{\lambda_n} \langle l, \nu \rangle$
 $\Rightarrow \langle l, \nu \rangle \xrightarrow{\lambda_1} \dots \xrightarrow{\lambda_n} \langle l, \nu \rangle$
 by $\xrightarrow{t_1} \dots \xrightarrow{t_n} \xrightarrow{\alpha_1}$

Decidability of The Location Reachability Problem

Claim: (Theorem 4.33)

The location reachability problem is **decidable** for timed automata.

Approach: Constructive proof.

✓ Observe: clock constraints are **simple**

→ w.l.o.g. assume constants $c \in \mathbb{N}_0$

✓ **Def. 4.19: time-abstract transition system** $U(\mathcal{A})$ — abstracts from uncountably many delay transitions, still infinite-state

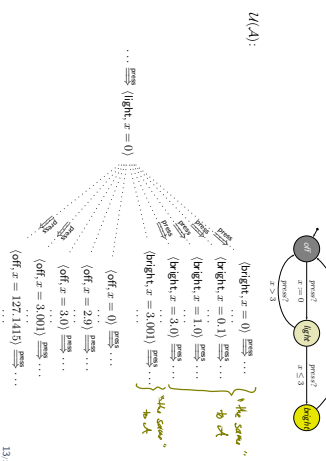

✓ **LEM. 4.20:** location reachability of \mathcal{A} is preserved in $U(\mathcal{A})$.

✗ **Def. 4.29: region automaton** $R(\mathcal{A})$ — equivalent configurations collapse into regions

✗ **LEM. 4.32:** location reachability of $U(\mathcal{A})$ is preserved in $R(\mathcal{A})$.

✗ **LEM. 4.28:** $R(\mathcal{A})$ is finite.

Indistinguishable Configurations

Distinguishing Clock Valuations: One Clock

• Assume \mathcal{A} with only a single clock, i.e. $X = \{x\}$ (recall: $C(\mathcal{A}) \subset \mathbb{N}$)

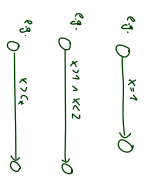

• \mathcal{A} could detect, for a given v_i whether $v_j(x) \in \{0, \dots, c_2\}$.

• \mathcal{A} cannot distinguish v_1 and v_2 if $v_i(x) \in (k, k+1)$, $i = 1, 2$ and $k \in \{0, \dots, c_2 - 1\}$.

• \mathcal{A} cannot distinguish v_1 and v_2 if $v_i(x) > c_2$, $i = 1, 2$.

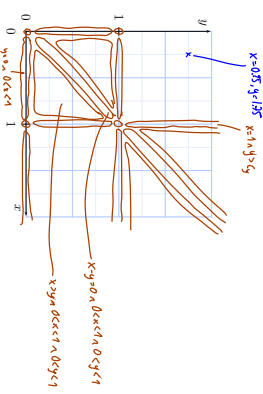

• If $c_2 \geq 1$, there are $(2c_2 + 2)$ equivalence classes: $\{0\}, \{0, 1\}, \{1\}, \{1, 2\}, \dots, \{c_2, \infty\}$

If $v_1(x)$ and $v_2(x)$ are in the same equivalence class, then v_1 and v_2 are indistinguishable by \mathcal{A} .

Distinguishing Clock Valuations: Two Clocks

• $X = \{x, y\}$, $c_2 = 1$, $c_y = 1$.

Distinguishing Clock Valuations: One Clock

• Assume \mathcal{A} with only a single clock, i.e. $X = \{x\}$ (recall: $C(\mathcal{A}) \subset \mathbb{N}$)

• \mathcal{A} could detect, for a given v_i whether $v_j(x) \in \{0, \dots, c_2\}$.

• \mathcal{A} cannot distinguish v_1 and v_2 if $v_i(x) \in (k, k+1)$, $i = 1, 2$ and $k \in \{0, \dots, c_2 - 1\}$.

• \mathcal{A} cannot distinguish v_1 and v_2 if $v_i(x) > c_2$, $i = 1, 2$.

Helper: Floor and Fraction

• Recall:

Each $q \in \mathbb{R}_0^+$ can be split into

• floor $\lfloor q \rfloor \in \mathbb{N}_0$ and

• fraction $\text{frac}(q) \in [0, 1)$

such that $q = \lfloor q \rfloor + \text{frac}(q)$.

An Equivalence-Relation on Valuations

Definition. Let X be a set of clocks, $c_a \in \mathbb{N}_0$ for each clock $x \in X$, and v_1, v_2 clock valuations of X .

We set $v_1 \cong v_2$ iff the following **four** conditions are satisfied.

- (1) For all $x \in X$:

$$|v_1(x)| = |v_2(x)| \text{ or both } v_1(x) > c_x \text{ and } v_2(x) > c_x.$$
 - (2) For all $x \in X$ with $v_1(x) \leq c_x$:

$$frac(v_1(x)) = 0 \text{ if and only if } frac(v_2(x)) = 0.$$
 - (3) For all $x, y \in X$:

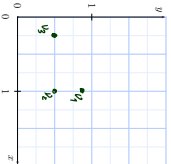

$$|v_1(x) - v_1(y)| = |v_2(x) - v_2(y)|$$
 or both $|v_1(x) - v_1(y)| > c_x$ and $|v_2(x) - v_2(y)| > c_x$.
 - (4) For all $x, y \in X$ with $-c_x \leq v_1(x) - v_1(y) \leq c_x$:

$$frac(v_1(x) - v_1(y)) = 0 \text{ if and only if } frac(v_2(x) - v_2(y)) = 0.$$
- Where $c = \max\{c_x, c_y\}$.

17/n

Example: Regions

- (1) $\forall x \in X : |v_1(x)| = |v_2(x)| \vee (v_1(x) > c_x \wedge v_2(x) > c_x)$
 $\iff frac(v_1(x)) = 0 \iff frac(v_2(x)) = 0$
- (2) $\forall x \in X : v_1(x) \leq c_x$
 $\iff frac(v_1(x)) = 0 \iff frac(v_2(x)) = 0$
- (3) $\forall x, y \in X : |v_1(x) - v_1(y)| = |v_2(x) - v_2(y)|$
 $\vee (|v_1(x) - v_1(y)| > c_x \wedge |v_2(x) - v_2(y)| > c_x)$
- (4) $\forall x, y \in X : -c_x \leq v_1(x) - v_1(y) \leq c_x$
 $\iff frac(v_1(x) - v_1(y)) = 0 \iff frac(v_2(x) - v_2(y)) = 0$

$v_1 \cong v_2$ because $|v_1(x)| = 0 \neq v_2(x)$

18/n

The Region Automaton

Definition 4.29. [Region Automaton] The **region automaton** $\mathcal{R}(\mathcal{A})$ of the timed automaton \mathcal{A} is the labelled transition system

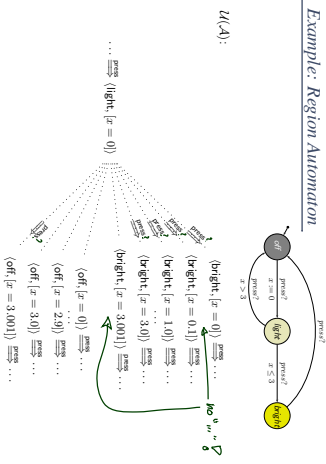

$$\mathcal{R}(\mathcal{A}) = (Conf(\mathcal{R}(\mathcal{A})), B_H, \{\xrightarrow{\alpha}_{R(\mathcal{A})} \mid \alpha \in B_H\}, C_{min})$$

- where
- $Conf(\mathcal{R}(\mathcal{A})) = \{(l, \nu) \mid l \in L, \nu : X \rightarrow \text{Time}, \nu \models I(l)\}$,
 where $I(l) = \{l, \nu \mid \nu \models \alpha, \alpha \in B_H\}$.
 - For each $\alpha \in B_H$:
 $(l, \nu) \xrightarrow{\alpha}_{R(\mathcal{A})} (l', \nu')$ if and only if $(l, \nu) \xrightarrow{\alpha}_{\mathcal{A}} (l', \nu')$
 in \mathcal{A} , and
 - $C_{min} = \{(l_{min}, [v_{min}]) \cap Conf(\mathcal{R}(\mathcal{A})) \text{ with } v_{min}(X) = \{0\}\}$.

Proposition. The transition relation of $\mathcal{R}(\mathcal{A})$ is well-defined that is, independent of the choice of the representative ν of a region $[v]$.

20/n

Example: Region Automaton

21/n

Regions

Proposition. \cong is an equivalence relation.

Definition 4.27. For a given valuation ν we denote by $[v]$ the equivalence class of ν . We call equivalence classes of \cong **regions**.

i.e. $\{\nu' \mid \nu' \cong \nu\}$

19/n

Remark

Remark 4.30. That a configuration (l, ν) is reachable in $\mathcal{R}(\mathcal{A})$ represents the fact, that all (l, ν) are reachable.
 In \mathcal{A} we can observe ν when location l has just been entered (no delay after entering).
 The clock values reachable by staying/letting time pass in l are **not explicitly** represented by the regions of $\mathcal{R}(\mathcal{A})$.

22/n

Decidability of The Location Reachability Problem

Claim: (Theorem 4.33)

The location reachability problem is **decidable** for timed automata.

Approach: Constructive proof.

- ✓ Observe: clock constraints are **simple**
— w.l.o.g. assume constants $c \in \mathbb{N}_0$.

✓ Def. 4.19: **time-abstract transition system** $\mathcal{U}(\mathcal{A})$ — abstracts from uncountably many delay transitions, still infinite-state.

✓ Lem. 4.20: location reachability of \mathcal{A} is preserved in $\mathcal{U}(\mathcal{A})$.

✓ Def. 4.29: **region automaton** $\mathcal{R}(\mathcal{A})$ — equivalent configurations collapse into regions

✓ Lem. 4.32: location reachability of $\mathcal{U}(\mathcal{A})$ is preserved in $\mathcal{R}(\mathcal{A})$.

✗ Lem. 4.28: $\mathcal{R}(\mathcal{A})$ is finite.

Region Automaton Properties

Lemma 4.32: [Correctness] For all locations ℓ of a given timed automaton \mathcal{A} the following holds:

ℓ is reachable in $\mathcal{U}(\mathcal{A})$ if and only if ℓ is reachable in $\mathcal{R}(\mathcal{A})$.

For the Proof:

Definition 4.21: [Bisimulation] An equivalence relation \sim on valuations is a (strong) **bisimulation** if and only if, whenever

$$v_1 \sim v_2 \text{ and } (v_1) \xrightarrow{c, \delta} (v_1')$$

then there exists v_2' with $(v_2) \xrightarrow{c, \delta} (v_2')$ and $(v_1') \sim (v_2')$.

Lemma 4.26: [Bisimulation] \cong is a strong bisimulation.

The Number of Regions

Lemma 4.28: Let X be a set of docks $c_x \in \mathbb{N}_0$ the maximal constant for each $x \in X$, and $c = \max\{c_x \mid x \in X\}$. Then

$$(2c + 2)^{|X|} \cdot (4c + 3)^{\sum_{x \in X} (c_x - 1)}$$

is an upper bound on the number of regions.

Proof: [Olderog and Dierkes, 2008]

*regions of X
(number of elements in X)*

Observations Regarding the Number of Regions

• Lemma 4.28 in particular tells us that each timed automaton (in our definition) has **finitely** many regions.

• Note: the upper bound is a worst case, not an exact bound.

$$|L| \cdot \underbrace{|R_{\text{equiv}}|}_{\in \{2c+2\}^{|X|} \dots}$$

$$\begin{aligned} \mathcal{L}_1: L_1, X_1 & \quad \bullet 2^{|L_1|} \cdot |L_1| \\ \mathcal{L}_2: L_2, X_2 & \quad \bullet 2^{|L_2|} \cdot |L_2| \end{aligned}$$

Decidability of The Location Reachability Problem

Claim: (Theorem 4.33)

The location reachability problem is **decidable** for timed automata.

Approach: Constructive proof.

- ✓ Observe: clock constraints are **simple**
— w.l.o.g. assume constants $c \in \mathbb{N}_0$.

✓ Def. 4.19: **time-abstract transition system** $\mathcal{U}(\mathcal{A})$ — abstracts from uncountably many delay transitions, still infinite-state.

✓ Lem. 4.20: location reachability of \mathcal{A} is preserved in $\mathcal{U}(\mathcal{A})$.

✓ Def. 4.29: **region automaton** $\mathcal{R}(\mathcal{A})$ — equivalent configurations collapse into regions

✓ Lem. 4.32: location reachability of $\mathcal{U}(\mathcal{A})$ is preserved in $\mathcal{R}(\mathcal{A})$.

✗ Lem. 4.28: $\mathcal{R}(\mathcal{A})$ is finite.

Decidability of The Location Reachability Problem

Claim: (Theorem 4.33)

The location reachability problem is **decidable** for timed automata.

Approach: Constructive proof.

- ✓ Observe: clock constraints are **simple**
— w.l.o.g. assume constants $c \in \mathbb{N}_0$.

✓ Def. 4.19: **time-abstract transition system** $\mathcal{U}(\mathcal{A})$ — abstracts from uncountably many delay transitions, still infinite-state.

✓ Lem. 4.20: location reachability of \mathcal{A} is preserved in $\mathcal{U}(\mathcal{A})$.

✓ Def. 4.29: **region automaton** $\mathcal{R}(\mathcal{A})$ — equivalent configurations collapse into regions

✓ Lem. 4.32: location reachability of $\mathcal{U}(\mathcal{A})$ is preserved in $\mathcal{R}(\mathcal{A})$.

✓ Lem. 4.28: $\mathcal{R}(\mathcal{A})$ is finite.

Let $\mathcal{A} = (L, B, X, I, E, k_{min})$ be a timed automaton, $l \in L$ a location.

- $\mathcal{R}(\mathcal{A})$ can be constructed effectively.
- There are finitely many locations in L (by definition).
- There are finitely many regions by Lemma 4.28.
- So $Conf(\mathcal{R}(\mathcal{A}))$ is finite (by construction).
- It is decidable whether $Conf(\mathcal{R}(\mathcal{A}))$ is empty or whether there exists a sequence

$$\langle l_{min}, [r_{min}] \rangle \xrightarrow{\alpha} \mathcal{R}(\mathcal{A}) \langle l_1, [r_1] \rangle \xrightarrow{\alpha} \mathcal{R}(\mathcal{A}) \dots \xrightarrow{\alpha} \mathcal{R}(\mathcal{A}) \langle l_n, [r_n] \rangle$$

such that $l_n = l$ (reachability in graphs).

So we have

Theorem 4.33. [Decidability]
The location reachability problem for timed automata is decidable.
