Lecture 16: The Universality Problem for TBA

2011-07-19

Dr. Bernd Westphal

Albert-Ludwigs-Universität Freiburg, Germany

Contents & Goals

Last Lecture:

- Using Uppaal to check whether a TA satisfies a DC requirement
- Testable DC properties

This Lecture:

- Educational Objectives:** Capabilities for following tasks/questions.
 - What's a TBA and what's the difference to (extended) TA?
 - What's undecidable for timed (Büchi) automata?
 - What's the idea of the proof?

Content:

- Timed Büchi Automata and timed regular languages [Alur and Dill, 1994].
- The Universality Problem is undecidable for TBA [Alur and Dill, 1994]
- Why this is unfortunate.
- Timed regular languages are not everything.

2/n

... vs. Timed Automata

$\xi = ((\text{off}, 0), 0) \xrightarrow{1} (\text{off}, 1), 1$
 $\xrightarrow{2} (\text{light}, 0), 1 \xrightarrow{3} (\text{light}, 3), 4$
 $\xrightarrow{4} (\text{light}, 3), 4 \dots$

ξ is a computation path and run of \mathcal{A} .

4/n

New: Given a **timed word**
 $(a, 1), (b, 2), (a, 3), (b, 4), (a, 5), (b, 6), \dots$
 does \mathcal{A} accept it?

New: acceptance criterion is **visiting accepting state infinitely often.**

4/n

Timed Languages

Definition. A time sequence $\tau = \tau_1, \tau_2, \dots$ is an infinite sequence of time values $\tau_i \in \mathbb{R}_0^+$, satisfying the following constraints:

- Monotonicity:** τ increases **strictly** monotonically, i.e. $\tau_i < \tau_{i+1}$ for all $i \geq 1$.
- Progress:** For every $i \in \mathbb{N}_0^+$, there is some $i' \geq 1$ such that $\tau_{i'} > i$.

infinite sequence of ticks from Σ

Definition. A **timed word** over an alphabet Σ is a pair (σ, τ) where

- $\sigma = \sigma_1, \sigma_2, \dots \in \Sigma^\omega$ is an **infinite** word over Σ , and
- τ is a time sequence.

Definition. A **timed language** over an alphabet Σ is a set of timed words over Σ .

5/n

Timed Büchi Automata

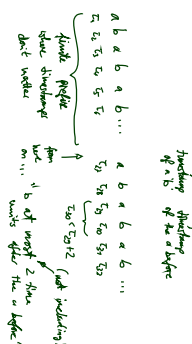

Alur and Dill, 1994

Example: Timed Language

Timed word over alphabet Σ a pair (σ, τ) where

- $\sigma = \sigma_1, \sigma_2, \dots$ is an infinite word over Σ , and
- τ is a time sequence (strictly (1) monotonic, non-zero)

$$L_{\text{off}} = \{ ((ab)^n, \tau) \mid \exists n \forall i \geq 1: (\tau_{2i} < \tau_{2i-1} + 2) \}$$

6/n

Timed Buchi Automata

Definition. The set $\Phi(X)$ of clock constraints over X is defined inductively by $\delta := x \leq c \mid c \leq x \mid \neg \delta \mid \delta_1 \wedge \delta_2$ where $x \in X$ and $c \in \mathbb{Q}$ is a rational constant.

Definition. A timed Buchi automaton (TBA) \mathcal{A} is a tuple $(\Sigma, S, S_0, X, E, F)$, where

- Σ is an alphabet,
- S is a finite set of states, $S_0 \subseteq S$ is a set of start states,
- X is a finite set of clocks, and
- $E \subseteq S \times S \times \Sigma \times 2^X \times \Phi(X)$ gives the set of transitions.

An edge $(s, s', a, \lambda, \delta)$ represents a transition from state s to state s' on input symbol a . The set $\lambda \subseteq X$ gives the clocks to be reset with this transition, and δ is a clock constraint over X .

$F \subseteq S$ is a set of accepting states.

Example: TBA

$\mathcal{A} = (\Sigma, S, S_0, X, E, F)$
 $(s, s', a, \lambda, \delta) \in E$

(Accepting) TBA Runs

Definition. A run r , denoted by (s, ρ) , of a TBA $(\Sigma, S, S_0, X, E, F)$ over a timed word (σ, τ) is an infinite sequence of the form $r := (s_0, t_0) \xrightarrow{\sigma_1, \tau_1} (s_1, t_1) \xrightarrow{\sigma_2, \tau_2} (s_2, t_2) \xrightarrow{\sigma_3, \tau_3} \dots$ with $s_i \in S$ and $t_i : X \rightarrow \mathbb{R}_+^+$ satisfying the following requirements:

- **Initiation:** $s_0 \in S_0$ and $r(c) = 0$ for all $c \in X$.
- **Consistency:** For all $i \geq 1$ there is an edge in E of the form $(s_{i-1}, s_i, \sigma_i, \lambda_i, \delta_i)$ such that $(s_{i-1}, t_{i-1}, \sigma_i, \tau_i, \lambda_i, \delta_i)$ satisfies δ_i and $t_i = (t_{i-1} + (\tau_i - \tau_{i-1})) \setminus \lambda_i = 0$.

The set $\text{inf}(r) \subseteq S$ consists of those states $s \in S$ such that $s = s_i$ for infinitely many $i \geq 0$.

Definition. A run $r = (s, \rho)$ of a TBA over timed word (σ, τ) is called (an) accepting (run) if and only if $\text{inf}(r) \cap F \neq \emptyset$.

Example: (Accepting) Runs

$r := (s_0, t_0) \xrightarrow{\sigma_1, \tau_1} (s_1, t_1) \xrightarrow{\sigma_2, \tau_2} (s_2, t_2) \xrightarrow{\sigma_3, \tau_3} \dots$ initial and $(s_{i-1}, t_{i-1}, \sigma_i, \tau_i, \lambda_i, \delta_i) \in E, s_i \in S, (t_{i-1} + (\tau_i - \tau_{i-1})) \setminus \lambda_i = 0$ Accepting if $\text{inf}(r) \cap F \neq \emptyset$

Timed word: $(a, 1), (b, 0), (a, 2), (b, 3), (a, 3), (b, 0), \dots$

- Can we construct any run? Is it accepting?
- $r := (s_0, t_0) \xrightarrow{\sigma_1, \tau_1} (s_1, t_1) \xrightarrow{\sigma_2, \tau_2} (s_2, t_2) \xrightarrow{\sigma_3, \tau_3} (s_3, t_3) \xrightarrow{\sigma_4, \tau_4} \dots$
 $\text{inf}(r) = \{s_1, s_3\}$, r is accepting since $\text{inf}(r) \cap F = \{s_3\} \neq \emptyset$
- Can we construct a non-run? many violations
- $r' := (s_0, 0) \xrightarrow{\sigma_1, \tau_1} (s_2, 1) \xrightarrow{\sigma_2, \tau_2} (s_3, 2) \xrightarrow{\sigma_3, \tau_3} (s_3, 3) \rightarrow \dots$
- Can we construct a (non-)accepting run?

(Accepting) TBA Runs

Definition. A run r , denoted by (s, ρ) , of a TBA $(\Sigma, S, S_0, X, E, F)$ over a timed word (σ, τ) is an infinite sequence of the form $r := (s_0, t_0) \xrightarrow{\sigma_1, \tau_1} (s_1, t_1) \xrightarrow{\sigma_2, \tau_2} (s_2, t_2) \xrightarrow{\sigma_3, \tau_3} \dots$ with $s_i \in S$ and $t_i : X \rightarrow \mathbb{R}_+^+$ satisfying the following requirements:

- **Initiation:** $s_0 \in S_0$ and $r(c) = 0$ for all $c \in X$.
- **Consistency:** for all $i \geq 1$, there is an edge in E of the form $(s_{i-1}, s_i, \sigma_i, \lambda_i, \delta_i)$ such that $(s_{i-1}, t_{i-1}, \sigma_i, \tau_i, \lambda_i, \delta_i)$ satisfies δ_i and $t_i = (t_{i-1} + (\tau_i - \tau_{i-1})) \setminus \lambda_i = 0$.

Handwritten notes: "Have state" pointing to s_2 , "How would this look since reaching (s_2, t_2) ?"

The Language of a TBA

Definition. For a TBA \mathcal{A} , the language $L(\mathcal{A})$ of timed words it accepts is defined to be the set $\{(\sigma, \tau) \mid \mathcal{A} \text{ has an accepting run over } (\sigma, \tau)\}$. For short: $L(\mathcal{A})$ is the language of \mathcal{A} .

Definition. A timed language L is a timed regular language if and only if $L = L(\mathcal{A})$ for some TBA \mathcal{A} .

Example: Language of a TBA

$L(A) = \{(a^x b^y) \mid A \text{ has an accepting run over } (a^x b^y)\}$.

Claim:

$$L(A) = L_{rec} = \{(a^i b^j) \mid \exists \forall j \geq i : (r_{2j} \leq r_{2j-1} + 2)\}$$

- $L_{acc} \subseteq L(A)$: "ok, can't find $a \in L_{acc}$. Construct an accepting run on $a^i b^j$.
- $L(A) \subseteq L_{acc}$: "ok, can't find $a \in L(A)$, then there is an accepting run. (3:57) on (a^i b^j).

Question: Is L_{rec} timed regular or not?

The Universality Problem is Undecidable for TBA

[Aur and Dil, 1994]

The Universality Problem

- Given: A TBA A over alphabet Σ .
 - Question: Does A accept all timed words over Σ^* ?
- In other words: Is $L(A) = \{(a^x b^y) \mid \sigma \in \Sigma^*, \tau \text{ time sequence}\}$.

The Universality Problem

- Given: A TBA A over alphabet Σ .
 - Question: Does A accept all timed words over Σ^* ?
- In other words: Is $L(A) = \{(a^x b^y) \mid \sigma \in \Sigma^*, \tau \text{ time sequence}\}$.

Theorem 5.2. The problem of deciding whether a timed automaton over alphabet Σ accepts all timed words over Σ^* is Π_1^1 -hard.

(The class Π_1^1 consists of highly undecidable problems, including some nonarithmetical sets (for an exposition of the analytical hierarchy consult, for instance Rogers, 1987).)

Recall: With classical Buchi Automata (untimed), this is different:

- Let B be a Buchi Automaton over Σ . $\overline{L(B)}$ is Σ^* -complete on Σ^* .
- B is universal iff and only if $L(B) = \emptyset$.
- B' such that $L(B') = \overline{L(B)}$ is effectively computable.
- Language emptiness is decidable for Buchi Automata.

Proof Idea

Theorem 5.2. The problem of deciding whether a timed automaton over alphabet Σ accepts all timed words over Σ^* is Π_1^1 -hard.

Proof Idea:

- Consider a language L_{rec} which consists of the recurring computations of a 2-counter machine M .
- Construct a TBA A from M which accepts the complement of L_{rec} , i.e. with

$$L(A) = \overline{L_{rec}}$$

- Then A is universal iff and only if L_{rec} is empty...
- ... which is the case iff and only if M doesn't have a recurring computation.

Once Again: Two Counter Machines (Different Flavour)

- A two-counter machine M
 - has two counters C, D and
 - a finite program consisting of n instructions, call one of $c_1 a_1 b_1$.
 - An instruction increments or decrements one of the counters, or jumps, here even non-deterministically.
- A configuration of M is a triple (i, c, d) : program counter $i \in \{1, \dots, n\}$, values $c, d \in \mathbb{N}_0$ of C and D .
- A computation of M is an infinite consecutive sequence

$$(1, 0, 0) = (c_0, c_0, d_0), (i_1, c_1, d_1), (i_2, c_2, d_2), \dots$$

that is, $(i_{j+1}, c_{j+1}, d_{j+1})$ is a result executing instruction i_j at (i_j, c_j, d_j) .

A computation of M is called recurring iff $i_j = 1$ for infinitely many $j \in \mathbb{N}_0$.

Step 1: The Language of Recurring Computations

- Let M be a ZCM with n instructions.

Wanted: A timed language L_{timed} (over some alphabet) representing exactly the recurring computations of M . In particular such that $L_{\text{timed}} = \emptyset$ if and only if M has no recurring computation.

- Choose $\Sigma = \{b_1, \dots, b_n, a_1, a_2\}$ as alphabet.

- We represent a configuration $\{i, c, d\}$ of M by the sequence

$$b_1 \underbrace{01 \dots 01}_c \underbrace{02 \dots 02}_d = b_1 a_1^c a_2^d$$

Step 1: The Language of Recurring Computations

$\{i, c, d\}$ represented by $b_1 a_1^c a_2^d$

Let L_{timed} be the set of the timed words (σ, τ) with

- σ is of the form $b_1 a_1^c a_2^d b_1 a_2^c a_1^d \dots$
 - $\{(i, c, d), (i_2, c_2, d_2), \dots\}$ is a recurring computation of M .
 - For all $j \in \mathbb{N}^n$,
 - the time of b_j is j .
 - if $c_{j+1} = c_j$ then for every a_i at time t in the interval $[j, j+1]$ there is an a_i at time $t+1$.
 - if $c_{j+1} = c_j + 1$ then for every a_i at time t in the interval $[j+1, j+2]$ except for the last one, there is an a_i at time $t-1$.
 - if $c_{j+1} = c_j - 1$ then for every a_i at time t in the interval $[j, j+1]$ except for the last one, there is an a_i at time $t+1$.
- And analogously for the a_2 's.

Step 2: Construct "Observer" for L_{timed}

Wanted: A TBA \mathcal{A} such that

$$L(\mathcal{A}) = L_{\text{timed}}$$

Step 1: The Language of Recurring Computations

$\{i, c, d\}$ represented by $b_1 a_1^c a_2^d$

Let L_{timed} be the set of the timed words (σ, τ) with

- σ is of the form $b_1 a_1^c a_2^d b_1 a_2^c a_1^d \dots$
 - $\{(i, c, d), (i_2, c_2, d_2), \dots\}$ is a recurring computation of M .
 - For all $j \in \mathbb{N}^n$,
 - the time of b_j is j .
 - if $c_{j+1} = c_j$ then for every a_i at time t in the interval $[j, j+1]$ there is an a_i at time $t+1$.
 - if $c_{j+1} = c_j + 1$ then for every a_i at time t in the interval $[j+1, j+2]$ except for the last one, there is an a_i at time $t-1$.
 - if $c_{j+1} = c_j - 1$ then for every a_i at time t in the interval $[j, j+1]$ except for the last one, there is an a_i at time $t+1$.
- And analogously for the a_2 's.

Step 2: Construct "Observer" for L_{timed}

Wanted: A TBA \mathcal{A} such that

$$L(\mathcal{A}) = L_{\text{timed}}$$

What are the reasons for a timed word **not to be** in L_{timed} ?

- The b_i at time $j \in \mathbb{N}$ is missing, or there is a spurious b_i at time $t \notin [j, j+1]$.
- The prefix of the timed word with times $0 \leq t < 1$ doesn't encode $(1, 0, 0)$.
- The timed word is not recurring, i.e. it has only finitely many b_i .
- The configuration encoded in $[j+1, j+2]$ doesn't faithfully represent the effect of instruction b_i on the configuration encoded in $[j, j+1]$.

Plan: Construct a TBA \mathcal{A}_0 for case (i), a TBA \mathcal{A}_{rec} for case (ii), a TBA $\mathcal{A}_{\text{recur}}$ for case (iii), and one TBA \mathcal{A}_i for each instruction for case (iv).

Then set

$$\mathcal{A} = \mathcal{A}_0 \cup \mathcal{A}_{\text{rec}} \cup \mathcal{A}_{\text{recur}} \cup \bigcup_{1 \leq i \leq n} \mathcal{A}_i$$

Step 2.(i): Construct A_0

(i) The b_0 at time $j \in \mathbb{N}$ is missing, or there is a spurious b_0 at time $t \in [j, j+1[$.

[Aur and Dill, 1994]: "It is easy to construct such a timed automaton."

Step 2.(ii): Construct A_{init}

(ii) The prefix of the timed word with times $0 \leq t < 1$ doesn't encode $(1, 0, 0)$.

• It accepts

$$\{(\sigma_j, \tau_j)_{j \in \mathbb{N}_0} \mid (a_0 \neq b_1) \vee (a_0 \neq 0) \vee (a_1 \neq 1)\}$$

Step 2.(iii): Construct A_{finite}

(iii) The timed word is not recurring, i.e. it has only finitely many b_0 .

• A_{finite} accepts words with only finitely many b_0 .

Step 2.(iv): Construct A_1

(iv) The configuration encoded in $[j+1, j+2[$ doesn't faithfully represent the effect of instruction b_0 on the configuration encoded in $[j, j+1[$.

Example: assume instruction 7 is

Increment counter D and jump non-deterministically to instruction 3 or 5.

Once again: stepsize: A_1 is $A_1^1 \cup \dots \cup A_1^k$.

Step 2.(iv): Construct A_1

(iv) The configuration encoded in $[j+1, j+2[$ doesn't faithfully represent the effect of instruction b_0 on the configuration encoded in $[j, j+1[$.

Example: assume instruction 7 is

Increment counter D and jump non-deterministically to instruction 3 or 5.

Once again: stepsize: A_1 is $A_1^1 \cup \dots \cup A_1^k$.

- A_1^k accepts words with b_1 at time j but neither b_0 nor b_2 at time $j+1$. "Easy to construct."

Step 2.(iv): Construct A_1

(iv) The configuration encoded in $[j+1, j+2[$ doesn't faithfully represent the effect of instruction b_0 on the configuration encoded in $[j, j+1[$.

Example: assume instruction 7 is

Increment counter D and jump non-deterministically to instruction 3 or 5.

Once again: stepsize: A_1 is $A_1^1 \cup \dots \cup A_1^k$.

- A_1^k accepts words with b_1 at time j but neither b_0 nor b_2 at time $j+1$. "Easy to construct."
- A_1^k is

Step 2.(iv): Construct \mathcal{A}

(iv) The configuration encoded in $[j+1, j+2]$ doesn't faithfully represent the effect of instruction b_j on the configuration encoded in $[j, j+1]$.

Example: assume instruction 7 is:

Increment counter D and jump non-deterministically to instruction 3 or 5. Once again: stepwise: \mathcal{A}^i is $\mathcal{A}^i \cup \dots \cup \mathcal{A}^k$.

- \mathcal{A}^k accepts words with b_j at time j but neither b_j nor b_k at time $j+1$. "Easy to construct."
- \mathcal{A}^k is

- \mathcal{A}^k accepts words which encode unexpected increment of counter C .
- $\mathcal{A}^k \dots \mathcal{A}^k$ accept words with missing decrement of D .

Aha, And...?

Consequences: Language Inclusion

- Given:** Two TBAs \mathcal{A}_1 and \mathcal{A}_2 over alphabet B .
- Question:** Is $L(\mathcal{A}_1) \subseteq L(\mathcal{A}_2)$?

Possible applications of a decision procedure:

- Characterise the allowed behaviour as \mathcal{A}_2 and model the design as \mathcal{A}_1 .
- Automatically check whether the behaviour of the design is a subset of the allowed behaviour.

- If **language inclusion** was decidable, then we could use it to decide universality of \mathcal{A} by checking

$$L(\mathcal{A}_{\text{min}}) \subseteq L(\mathcal{A})$$

where \mathcal{A}_{min} is any universal TBA (which is easy to construct)

Consequences: Complementation

- Given:** A timed regular language W over B (that is, there is a TBA \mathcal{A} such that $L(\mathcal{A}) = W$).
- Question:** Is \overline{W} timed regular?

Possible applications of a decision procedure:

- Characterise the allowed behaviour as \mathcal{A}_2 and model the design as \mathcal{A}_1 .
- Automatically construct \mathcal{A}_2 with $L(\mathcal{A}_2) = \overline{L(\mathcal{A}_1)}$ and check

$$L(\mathcal{A}_1) \cap L(\mathcal{A}_2) = \emptyset$$

- that is, whether the design has any non-allowed behaviour.
- Taking for granted that:
 - The intersection automaton is effectively computable.
 - The emptiness problem for Buchi automata is **decidable** (Proof by construction of region automaton [Aur and Dill, 1994])

Consequences: Language Inclusion

- Given:** Two TBAs \mathcal{A}_1 and \mathcal{A}_2 over alphabet B .
- Question:** Is $L(\mathcal{A}_1) \subseteq L(\mathcal{A}_2)$?

Possible applications of a decision procedure:

- Characterise the allowed behaviour as \mathcal{A}_2 and model the design as \mathcal{A}_1 .
- Automatically check whether the behaviour of the design is a subset of the allowed behaviour.

Consequences: Complementation

- Given:** A timed regular language W over B (that is, there is a TBA \mathcal{A} such that $L(\mathcal{A}) = W$).
- Question:** Is \overline{W} timed regular?

Consequences: Complementation

- **Given:** A timed regular language IV over B (that is, there is a TBA \mathcal{A} such that $L(\mathcal{A}) = IV$).
- **Question:** Is IV^c timed regular?
- If the class of timed regular languages were closed under **complementation**, "the complement of the inclusion problem is recursively enumerable." This contradicts the II'-hardness of the inclusion problem." [Alur and Dill, 1994]

Consequences: Complementation

- **Given:** A timed regular language IV over B (that is, there is a TBA \mathcal{A} such that $L(\mathcal{A}) = IV$).
- **Question:** Is IV^c timed regular?
- If the class of timed regular languages were closed under **complementation**, "the complement of the inclusion problem is recursively enumerable." This contradicts the II'-hardness of the inclusion problem." [Alur and Dill, 1994]

A non-complementable TBA \mathcal{A} :

$$L(\mathcal{A}) = \{(a^x \cdot (a)_i)_{i \in \mathbb{N}_0} \mid \exists i \in \mathbb{N}_0 \exists j > i : (i_j = i + 1)\}$$

Complement language:

$$L(\mathcal{A})^c = \{(a^x \cdot (a)_i)_{i \in \mathbb{N}_0} \mid \text{no two } a \text{ are separated by distance 1}\}.$$

Beyond Timed Regular

Beyond Timed Regular

With clock constraints of the form

$$x + y \leq x' + y'$$

we can describe timed languages which are not timed regular.

In other words:

- There are strictly timed languages than timed regular languages.
- There exists timed languages L such that there exists no \mathcal{A} with $L(\mathcal{A}) = L$.

Example:
