

Recall: Test Case, Test Execution

The first diagram shows a test case structure with fields: **Test Case ID**, **Test Case Description**, **Test Case Pre-conditions**, **Test Case Post-conditions**, **Test Case Data**, and **Test Case Steps**. The second diagram shows a test execution flow: **Test Case** leads to **Test Case Execution**, which leads to **Test Case Results**. The third diagram shows a test case with **Test Case ID**, **Test Case Description**, **Test Case Pre-conditions**, **Test Case Post-conditions**, **Test Case Data**, and **Test Case Steps**.

The diagram illustrates a Program Execution Path (PEP) with a sequence of steps and decision points. It shows how a test case is executed and how the results are recorded.

Recall: Test Case, Test Execution

Not Executing Test Cases

- Consider the test case for procedure $arrLen$. (Empty string has length 0)
- A tester observes the following software behaviour:

$$\pi = \left\{ \begin{array}{l} (s \rightarrow \text{NULL}, r \rightarrow 0) \\ (s \rightarrow \text{""}, r \rightarrow 0) \end{array} \right\}$$

program-delta
- Test execution **positive** or **negative**?
 If/ II

- Note**
- If a tester does not adhere to an allowed input sequence of T , π is **not** a test execution. Thus π is neither positive nor negative (only defined for test execution).
 - Same case: power outage (if continuous power supply is considered in input sequence).

By The Way... (Good Design)

- High quality software should be aware of its specification, and "complain" if operated outside of specification, e.g.
 - throw an exception,
 - abort program execution,
 - (at least) print an error message,
 - etc.
- **Not:** "garbage in, garbage out"
- **Example:** `strlen(3)` (C standard)
 - Allowed input: sane C-strings; return value is an integer,
 - `strlen` is not a C-string!
 - Thus, on input `NULL`, "complain" instead of just return an arbitrary number or "crash".

- A **test suite** is a finite set of test cases (T_1, \dots, T_n) .
- An execution of a test suite is a set of computation paths, such that there is at least one execution for each test case.
- An execution of a test suite is called **positive** if and only if ALL QED test case execution is **positive**. Otherwise, it is called **negative**.

7/60

- **Systematic test** – a test such that
 - environmental conditions are defined or precisely documented
 - inputs have been chosen systematically
 - results have been assessed according to criteria that have been fixed before. (Ludwig and Ludner, 2013)

Test – one or multiple execution(s) of a program on a computer with the goal to find errors. (Ludwig and Ludner, 2013)

- **Not (even) a test** in the sense of this weak definition:
 - any inspection of the program (no execution),
 - demo of the program (other goal),
 - analysis of source code (for e.g. values of metrics (other goal),
 - investigation of the program with a debugger (other goal).

Our Synonyms for non-systematic tests: Experiment, Rumpcode!

In the following: test means systematic test; if not systematic: call it experiment.

8/60

9/60

Testing Vocabulary

10/60

Specific Testing Notions

- How are the test cases chosen?
 - Considering only the specification (black-box or function test)
 - Considering the structure of the test item (glass-box or structure test)
- How much effort is put into testing?
 - execution time – does the program do it all?
 - these many test – time spent and judgement on-the-fly, "I'm probably OK"
 - systematic test – somebody (not author) defines test cases, defines input/output, documents test execution.
- Experience: In the long run, **systematic tests** are more economic.
 - Complexity of the test item:
 - unit test – a single program unit is tested (function, sub-routine, method, class, etc.)
 - module test – a component is tested.
 - integration test – interactions between components is tested.
 - system test – tests a whole system.

11/60

Specific Testing Notions Cont'd

- Which property is tested?
 - function test – functionality as specified by the requirements documents.
 - installation test – is it possible to install the software with the provided documentation and tools?
 - recommissioning test – is it possible to bring the system back to operation after operation was stopped?
 - availability test – does the system run for the required amount of time without issues.
 - load and stress test – does the system behave as required under high or highest load? ... under overload? "Hey, sorry how many game objects can be loaded" ... "this is an experiment, not a test."
 - resource test – resource time, minimal hardware (software) requirements, etc.
 - regression test – a set of the software behaviour like the old one on input, where no behaviour change is expected?

12/60

Specific Testing Notions Cont'd

- Which roles are involved in testing?
 - Inhouse test – only developers (meaning: quality assurance role)
 - alpha and beta test – selected potential customers
 - acceptance test – the customer tests whether the system for parts of it, at mission-critical test whether the system is acceptable.

14/40

The Limits of Software Testing

15/40

Software Examination (in Particular Testing)

- In each examination, there are two paths from the specification to results:
 - the production path (using model, source code, executable, etc.) and
 - the examination path (by comparing specifications)
- A check can only discover errors on **every part** of the path.
- If a difference is detected, examination result is positive.
- What is not on the path, is not checked: crucial: **specification and comparison**

16/40

Recall: Quotes On Testing

“Software testing can be used to show the presence of bugs, but it cannot be used to show their absence.”
— **Richard M. Stallman**

(E.W. Dijkstra, 1970)

17/40

17/40

Why Can't We Show The Absence of Errors (in General)?

- Consider a simple pocket calculator for adding 8-digit decimals.
- Requirement: If the display shows $x + y$, then after pressing $+$ the sum of x and y is displayed if $x + y$ has at most 8 digits.
- otherwise “-E-” is displayed.
- With 8 digits, both x and y range over $[0, 10^8 - 1]$.
- Thus there are $10^{16} = 10,000,000,000,000,000$ possible input pairs (x, y) to be considered for exhaustive testing, i.e. testing every possible case!
- And if we restart the pocket calculator for each test, we've **not even begun** testing about problems with sequences of inputs... (local variables may not be reinitialized properly, for example)

18/40

Observation: Software Usually Has Many Inputs

- Example: Simple Pocket Calculator
- With ten thousand (10,000) different test cases (that's a lot!), 9,999,999,999,990,000 of the 10^{16} possible inputs remain **uncovered**
- In other words: Only 0.0000000001% of the possible inputs are covered, (0.0000000001% not touched)
- In diagrams: (red = uncovered, blue = covered)

Observation: Software Usually Has Many Inputs

- Example: Simple Pocket Calculator

Generic Requirements on Good Test Cases: Reproducibility

- Test executions should be (as) **reproducible** and **objective** (as possible)
- So, **strictly speaking**, a test case is a triple (I_n, S_{env}, E_{inv}) comprising a description I_n of **environmental conditions**
- E_{inv} describes any aspects which **could have an effect** on the outcome of a test execution and cannot be specified as part of I_n , such as
 - Which program (version) is tested?
 - Built with which compiler, linker, etc.?
 - Test host OS, architecture, memory size, connected devices (configurations), etc.?
 - Which other software (in which version, configuration) is involved?
 - Who is supposed to test when?
 - etc. etc.
- Full reproducibility is hardly possible in practice – obviously (er, why...?)
- Steps towards **reproducibility** and **objectivity**:
 - have a fixed build environment,
 - use a fixed test host which does not do any other jobs,
 - execute test cases **automatically** (test script)

How to Choose Test Cases?

- A first rule-of-thumb
 - Everything which is required, **must** be examined / checked. Otherwise it is uncertain whether the requirements have been understood and realized. (Kochling and Lohrer, 2013)
- In other words:
 - Not having
 - at least one systematic test case
 - for each (required) feature
 - is **(grossly?) negligent** (Dr. (good?) faithless!)
- In even other words
 - Without at least one test case for each feature, we can **hardly speak** of software engineering.
- Good project management: document for each test case which features it tests.

Choosing Test Cases

What Else Makes a Test Case a Good Test Case?

A test case is a good test case if it discovers - with high probability - an unknown error.

Accidental test case ($(I_n, S(n))$) would be

- of low redundancy, i.e. it does not test what other test cases also test.
- error sensitive, i.e. has high probability to detect an error. (Probability should at least be greater than 0)
- representative, i.e. represent a whole class of inputs. (i.e., software S passes $(I_n, S(n))$ if and only S behaves well for all I' from the class)

The idea of representative

12345678
9
0
1
2
3

- If $(12345678, 27)$, (12345700) was representative for $(0, 27; 27)$, $(1, 27; 28)$, etc.
- Then from a negative execution of test case $(12345678, 27)$, (12345700)
- we could conclude that $(0, 27; 27)$, etc. will be negative as well.

18/60

Point vs. Range Errors

Software is (in general) not continuous.

- Consider a continuous function, e.g. the one to the right
- For sufficiently small ϵ -environments of an input, the outputs differ only by a small amount δ .
- Physical systems are to a certain extent continuous.
- For example, if a bridge endures a single car of 1000 kg, we strongly expect the bridge to endure cars of 990 kg or 1010 kg.
- And anything of weight smaller than 1000 kg can be expected to be endured.

- For software, adjacent inputs may yield arbitrarily distinct output values.

Vocabulary

- Point error: an isolated input value triggers the error.
- Range error: multiple "neighbouring" inputs trigger the error.

- For software, we can (in general, without extra information) not conclude from some values to others.

26/60

What Else Makes a Test Case a Good Test Case?

Thus, The wish for representative test cases is **problematic**.

- In general, we do not know which inputs lie in an equivalence class w.r.t. a certain error.
- Yet there is a large body on literature on how to construct representative test cases, **assuming** we know the equivalence classes.
- Of course "if" we "know" equivalence classes, we should exploit that knowledge to optimise the number of test cases.

- But it is perfectly reasonable to test representatives of equivalence classes induced by the specification, e.g.
- valid and invalid inputs (to check whether input validation works at all)
- different classes of inputs considered in the requirements
- the "CSO"; "ET" coins in the vending machine \rightarrow have at least one test case with each.
- Recall: one should have at least one test case per feature.

27/60

Statistical Testing

29/60

29/60

One Approach: Statistical Tests

- Classical statistical testing is one approach to deal with
- in practice not exhaustively testable huge input space.
- tester bias.
- (people tend to choose "good" w.r.t. "inputs and disregard (bad?) corner-cases; recall: the developer is not a good tester)

Procedure:

- Randomly (\emptyset) choose test cases T_1, \dots, T_n , for test suite T .
- Execute test suite T .
- If an error is found:
- good, we certainly know there is an error.
- if no error is found:
- refine hypotheses "program is not correct" with a certain significance α -level.
- (significance α may be equidistant with similar test suites)
- (And Needs stochastical assumptions on error distribution and (only) random test cases)

30/60

(Ludewig and Uthner, 2013) name the following objections against statistical testing:

- In particular for **interactive software**, the primary requirement is often **to failures are experienced by the "typical user"**. Statistical testing (in general) may also cover a lot of "untypical user behaviours" unless sophisticated user-models are used.
- Statistical testing needs a method to compute "soft"-values for the randomly chosen inputs.
- That is easy for requirement "does not crash", but can be difficult in general.
- There is a high risk for **not finding point** or **small-range errors**. If they live in their "natural habitat", carefully crafted test cases would probably uncover them.

Findings in the literature can at best be called **inconclusive**.

31/00

Getting Soft Values

- Recall: A test case is a pair $(In, Soft)$ with proper expected for "soft" values. In a **formal world**, all "soft"-values are **defined** by the (formal) requirements specification and effectively **pre-computable**.
- In **this world**,
 - the formal requirements specification may only **reflectively** describe acceptable results without going a procedure to compute the results.
 - there may not be a formal requirements specification, e.g.
 - "the game objects should be rendered properly";
 - "the compiler must translate the program correctly";
 - "the notification message should appear on a proper screen position";
 - "the data must be available for at least 10 days";
 - etc.
- Then, need another instance to decide whether the observation is acceptable.
- The tester is **generally** prefers to call **any instance** which decides whether results are acceptable **for a given** test case.
 - In order **not to call** automatic derivation of "soft"-values from a **formal specification** an "oracle" (→ formal or fully described formal specification and single valid [precondition](#) [precondition](#) of the future, suggested by the book "Say Wikipedia").

34/00

Habitat-based Testing

- ### Choosing Test Cases Habitat-based
- Some traditional popular belief on software error habitat:
- Software errors (seem to) **enjoy**
 - **range boundaries**, e.g.
 - 0, 1, 27 (software works on input from [0, 27]);
 - 1, 28 (for error handling);
 - $-2^N - 1$ (on 32-bit architectures);
 - boundaries of arrays (last last element);
 - boundaries of loops (first, last iteration);
 - etc.
 - **special cases** of the problem (empty list, user-case without actor ...);
 - **special cases** of the programming language semantics;
 - **complex implementations**.
- **Good idea**: for each test case, note down why it has been chosen. For example: "demonstrate that corner-case handling is not completely broken".

Class-Box Testing: Coverage

- In the following, we assume that
 - S has a control flow graph (V, E, s, e) and statements $S \text{Stmts} \subseteq V$ and branches $C \text{Cnds} \subseteq E$.
 - each computation path prefix $s_0, s_1, \dots, s_{i-1}, s_i, \dots, s_n$ gives information on statements and control flow graph based edges which were executed right before obtaining s_i .

```

defn f : (Z × A)^V → Z^Stmts
  fun | (Z × A)^V → Z^Stmts
  1: let f (let s, let p, let e)
  2: | s_i | if (S > 100 / N) > 100
  3: | e | if (S > 100 / N) > 100
  4: | e | if (S > 100 / N) > 100
  5: | e | if (S > 100 / N) > 100
  6: | e | if (S > 100 / N) > 100
  7: | e | if (S > 100 / N) > 100
  8: | e | if (S > 100 / N) > 100
  9: | e | if (S > 100 / N) > 100
  10: | e | if (S > 100 / N) > 100
  end ()

  Stmt p = {s_0, s_1, s_2, s_3, s_4}
  Cnd f = {e_1, e_2, e_3, e_4}
  V / f/cds V / f/cds
  L / f/cds L / f/cds
  
```

Class-Box Testing: Coverage

- Coverage is a property of test cases and test suites
- Execution $\pi = (s_0, s_1, \dots, s_n)$ of test case T achieves p % statement coverage if and only if

$$p = \frac{|\text{Stmts}_{\text{exec}}(\pi)|}{|\text{Stmts}|} \cdot 100$$
- Test case T achieves p % statement coverage if and only if $p = \frac{100 \cdot |\text{Stmts}_{\text{exec}}(T)|}{|\text{Stmts}|}$
- Execution π of T achieves p % branch coverage if and only if

$$p = \frac{|\text{Cnds}_{\text{exec}}(\pi)|}{|\text{Cnds}|} \cdot 100$$
- Test case T achieves p % branch coverage if and only if $p = \frac{100 \cdot |\text{Cnds}_{\text{exec}}(T)|}{|\text{Cnds}|}$
- Define $p = 100$ for empty program. (Nepotically: $\text{Stmts} = \emptyset$ and $\text{Cnds} = \emptyset$, respectively)
- Statement/branch coverage canonically extends to test suite $T = \{T_1, \dots, T_n\}$. For example: $\text{gen}(T) = (s_0, \dots, s_n, s_{n+1}, \dots, s_{n+1})$ achieves

$$p = \frac{|\text{Union}_{i=1}^n \text{Stmts}_{\text{exec}}(T_i)|}{|\text{Stmts}|} \cdot 100$$

Indicate statements and branches of code (quality indicator) [9] (free or related concepts of the course) $s_0, e_1, e_2, e_3, e_4, s_1, s_2, s_3, s_4, s_5, s_6, s_7, s_8, s_9, s_{10}$ (added later for collection) and $s_0, e_1, e_2, e_3, e_4, s_1, s_2, s_3, s_4, s_5, s_6, s_7, s_8, s_9, s_{10}$ (added later for collection)

- In the following, we assume that
 - S has a control flow graph (V, E, s, e) and statements $S \text{Stmts} \subseteq V$ and branches $C \text{Cnds} \subseteq E$.
 - each computation path prefix $s_0, s_1, \dots, s_{i-1}, s_i, \dots, s_n$ gives information on statements and control flow graph based edges which were executed right before obtaining s_i .

```

defn f : (Z × A)^V → Z^Stmts
  fun | (Z × A)^V → Z^Stmts
  1: let f (let s, let p, let e)
  2: | s_i | if (S > 100 / N) > 100
  3: | e | if (S > 100 / N) > 100
  4: | e | if (S > 100 / N) > 100
  5: | e | if (S > 100 / N) > 100
  6: | e | if (S > 100 / N) > 100
  7: | e | if (S > 100 / N) > 100
  8: | e | if (S > 100 / N) > 100
  9: | e | if (S > 100 / N) > 100
  10: | e | if (S > 100 / N) > 100
  end ()

  Stmt p = {s_0, s_1, s_2, s_3, s_4}
  Cnd f = {e_1, e_2, e_3, e_4}
  
```

Coverage Example

```

let f (let s, let p, let e)
  1: if (S > 100 / N) > 100
  2: if (S > 100 / N) > 100
  3: if (S > 100 / N) > 100
  4: if (S > 100 / N) > 100
  5: if (S > 100 / N) > 100
  6: if (S > 100 / N) > 100
  7: if (S > 100 / N) > 100
  8: if (S > 100 / N) > 100
  9: if (S > 100 / N) > 100
  10: if (S > 100 / N) > 100
  end ()

Term Coverage

- Consider the statement

```
if (A) { if (B) { ... } } else { ... }
```

where A, \dots, B are minimal boolean terms, e.g. $x > 0$ but not $x \neq k$.

Branch coverage is easy in this case:

User has to run that $(A = 0, \dots, B = 1)$ and $(A = 1)$ such that $(A = 0, \dots, B = 1)$.

Additional goal:

check whether these are useful terms.

Term Coverage (for an expression $expr$):

Let $\beta = \{A_1, \dots, A_n\} \rightarrow B$ be a valuation of the terms.

Term A_i is *sketchable* in β for $expr$ if and only if

$\beta(A_i) = \text{sketch}[expr][\beta(A_i/m_{A_i})] \neq \text{sketch}[\beta(A_i/m_{A_i})]$

$\beta \in \{A_1, \dots, A_n\} \rightarrow B$ achieves β 's term coverage if and only if

$\beta = \{A_1, \dots, A_n\} \rightarrow B$ achieves β 's sketchable term coverage.

$\beta = \{A_1, \dots, A_n\} \rightarrow B$ achieves β 's sketchable term coverage.

$\beta = \{A_1, \dots, A_n\} \rightarrow B$ achieves β 's sketchable term coverage.

$\beta = \{A_1, \dots, A_n\} \rightarrow B$ achieves β 's sketchable term coverage.

$\beta = \{A_1, \dots, A_n\} \rightarrow B$ achieves β 's sketchable term coverage.

$\beta = \{A_1, \dots, A_n\} \rightarrow B$ achieves β 's sketchable term coverage.

$\beta = \{A_1, \dots, A_n\} \rightarrow B$ achieves β 's sketchable term coverage.

$\beta = \{A_1, \dots, A_n\} \rightarrow B$ achieves β 's sketchable term coverage.

Unreachable Code

```
int f(int x, int y, int z)
{
    if (x != 4)
        z = y / x;
    else
        z = x + 2;
    return z;
}
```

- Statement s is *never executed* because $x \neq x$ (loop false).
- this is *not* a statement / branch / term coverage and *not* *sketchable*.
- Assume evaluating $w()$ causes (undefined) abnormal program termination.
- Is statement s_1 an error in the program...?
- Term $s_1()$ is also back-critical.
- (In programming languages with short-circuit evaluation, it is never evaluated)

Conclusions from Coverage Measures

- Assume test suite T tests software S for the following property P :
 - pre-condition: P
 - post-condition: Qand S passes \emptyset T and the execution achieves 100% statement / branch / term coverage.
- What does this tell us about S ?
 - On which can we conclude from coverage measures?
- 100% statement coverage:
 - There is no statement which necessarily violates P .
 - There is no statement which necessarily violates Q .
 - There is no unreachable statement.
- 100% branch / term coverage:
 - There is no single branch / term which necessarily causes violations of P .
 - There is no single branch / term which necessarily causes violations of Q .
 - satisfying P where the condition / term evaluates to true, and/or to false.
 - There is no unused condition / term!

Not more (\leftarrow exercise!)
This definitely something, but not as much as "100%" may sound like...

Coverage Measures in Certification

- (Seems that) DO-178B:
 - Software Considerations in Airborne Systems and Equipment Certification" (which deals with the safety requirements that apply to certain airborne systems)
 - In particular, something's similar to *verification target* (VCT/DC coverage)
 - (Need to develop) process requirements, reviews, unit testing, etc.)
- If not required, ask: what is the effort / gain ratio? (average effort to detect an error term coverage needs high effort)
- Currently, the standard moves towards accepting certain verification or static analysis tools to support (or even replace) some testing obligations.

Tell Them What You've Told Them...

- A check can only discover errors on **exactly one path**.
- Software testing is challenging because
 - typically, huge input space
 - software is non-continuous
- There is a vast amount of literature on how to choose test cases.
 - A good starting point:
 - at least one test case per feature
 - corner-cases, extremal values
 - error handling, etc.
 - Class-box testing
 - considers the control flow graph
 - defines coverage measures
- Other approaches:
 - statistical testing, model-based testing
 - Define criteria for "testing done" (like coverage or cost per error)
 - Process: tester and developer should be different persons
