

Software Design, Modelling and Analysis in UML

Lecture 07: Class Diagrams II

2012-11-14

Prof. Dr. Andreas Podelski, Dr. Bernd Westphal
Albert-Ludwigs-Universität Freiburg, Germany

Contents & Goals

Last Lectures:

- class diagram — except for associations, visibility within OCL type system

This Lecture:

- Educational Objectives:** Capabilities for following tasks/questions
 - Please explain this class diagram with associations.
 - Which annotations of an association arrow are semantically relevant?
 - What's a role name? What's it good for?
 - What's "multiplicity"? How did we treat them semantically?
 - What is "reading direction", "navigability", "ownership", "...?
 - What's the difference between "aggregation" and "composition"?

Content:

- Complete visibility
- Study concrete syntax for "associations"
- (Temporarily) extend signature, define mapping from diagram to signature.
- Study effect on OCL
- Where do we put OCL constraints?

2:45

Casting in the Type System

3:00

One Possible Extension: Implicit Casts

- We may wish to have

$\vdash 1 \text{ and } \text{false} : \text{Bool}$

In other words: We may wish that the type system allows to use $0, 1 : \text{Int}$ instead of true and false without breaking well-typedness.

- Then just have a rule:

$$\frac{\Delta \vdash \text{expr} : \text{Bool}}{\vdash 1 - \text{expr} : \text{Bool}}$$

- With Cast (and Int , and Bool , and Fun), we can derive the sentence (*)

- But:** that's only half of the story — the definition of the interpretation function I that we have is not prepared, it doesn't tell us what (*) means...

4:55

Implicit Casts Cont'd

- So, why isn't there an interpretation for 1 and false?**

- First of all, we have (syntax)

$$\text{expr}_1 \text{ and } \text{expr}_2 : \text{Bool} \times \text{Bool} \rightarrow \text{Bool}$$

- Thus,

$$I(\text{and}) : I(\text{Bool}) \times I(\text{Bool}) \rightarrow I(\text{Bool})$$

where $I(\text{Bool}) = \{\text{true}, \text{false}\} \cup \{\perp_{\text{Bool}}\}$

- By definition,

$$I[\perp] \text{ and } \text{false}[\perp(\alpha, \beta)] = I(\text{and})(I[\perp](\alpha, \beta), I[\text{false}](\alpha, \beta)),$$

and there we're stuck.

5:55

Implicit Casts: Quickfix

- Explicitly define

$$I[\text{and}](\text{expr}_1, \text{expr}_2)(\alpha, \beta) := \begin{cases} b_1 \wedge b_2 & , \text{ if } b_1 \neq \perp_{\text{Bool}} \wedge b_2 \neq \perp_{\text{Bool}} \\ \perp_{\text{Bool}} & , \text{ otherwise} \end{cases}$$

where

- $b_1 := \text{toBool}(I[\text{expr}_1](\alpha, \beta))$,
- $b_2 := \text{toBool}(I[\text{expr}_2](\alpha, \beta))$,

and where

$$\text{toBool} : I(\text{Int}) \cup I(\text{Bool}) \rightarrow I(\text{Bool})$$

$$x \mapsto \begin{cases} \text{true} & , \text{ if } x \in \{\text{true}\} \\ \text{false} & , \text{ if } x \in \{\text{false}, 0\} \\ \perp_{\text{Bool}} & , \text{ otherwise} \end{cases}$$

6:00

Bottomline

- There are **wishes** for the type-system which require changes in both, the definition of τ and the type system. In most cases not difficult, but tedious.
- **Note:** the extension is still a basic type system.
- **Note:** OCL has a far more elaborate type system which in particular addresses the relation between *Decl* and *Inv* (cf. [7]).

Visibility in the Type System

Context

- **Example:** A problem?

- That is, whether an expression involving attributes with visibility is well-typed depends on the class of objects for which it is evaluated.
- **Therefore:** well-typedness in type environment Δ and context $B \in \mathcal{C}$:
 $\frac{\Delta, B \vdash expr : \tau}{\Delta, B \vdash expr : \tau}$ *well-typedness*
- In particular: prepare to treat "preceder" later (when doing inheritance)

Attribute Access in Context

- If $expr$ is of type τ in a type environment, then it is in **any context**:
 $\frac{\Delta \vdash expr : \tau}{Context(B) \vdash expr : \tau}$
- Accessing attribute v of a C -object via logical variable w is well-typed if $\langle v : \tau, \xi, expr_0, P_0 \rangle \in attr(B)$

- Accessing attribute v of a C -object of via expression $expr_1$ is well-typed in context B if $\langle v : \tau, \xi, expr_0, P_0 \rangle \in attr(C)$, $\xi = +$, or $C = B$.
- v is public, or $expr_1$ denotes an object of class B .
- Accessing $C_{0,1}^+$ or C_+ -typed attributes: similar.

Visibility — The Intuition

Let's study an Example:

Assume $w_1 : \tau$ and $w_2 : \tau_2$ are logical variables. Which of the following syntactically correct (?) OCL expressions shall we consider to be well-typed?

ξ of x :	public	private	protected	not	package
$w_1, n, x = 0$	✓ 1	✗ 1	?	✗ 1	?
$w_2, m, x = 0$	✓ 1	✗ 1	?	✗ 1	?

Context in Operator Application

(Context \mathcal{G})
 $\exists A \vdash \text{expr} : \tau$
 $\Delta \vdash \text{expr} : \tau$ (if $\tau \in \text{expr}$, P_0) is $\text{attr}(C)$
 $\Delta, B \vdash \text{expr} : \tau$ if $\tau = +$ or $\tau = -$ and $C = B$

Example:
 $\exists A \vdash \text{expr} : \tau$
 $\Delta \vdash \text{expr} : \tau$
 $\exists A \vdash \text{expr} : \tau$
 $\Delta \vdash \text{expr} : \tau$
 $\exists A \vdash \text{expr} : \tau$
 $\Delta \vdash \text{expr} : \tau$

- **Observation:**
 - Whether an expression **does** or **does not respect visibility** is a matter of well-typedness **only**.
 - We only evaluate (= apply I) to **well-typed** expressions.
- We need **not** adjust the interpretation function I to support visibility.

- Visibility is a property of attributes — is it useful to consider it in OCL?
- In other words: given the picture above, is it useful to state the following invariant? (even though x is private in D)

context $C \text{ inv} : n.r > 0$?
 (cf. [7], Sect. 12 and 9.2.2)

- **It depends.**
 - **Constraints and pre/post conditions:**
 - Visibility is sometimes not taken into account. To state “global” requirements, it may be adequate to have a “global view”, be able to look into all objects.
 - But: visibility supports “narrow interfaces”, “information hiding”, and similar good design practices. To be more robust against changes, try to state requirements only in the terms which are visible to a class.
 - Rule of thumb: if classes are separate but have requirements on design models, leave them public or provide getters/setters (also).
 - **Guards and operation bodies:**
 - If in doubt, **yes** (= do take visibility into account).
- Any so-called **action language** typically takes visibility into account.

Recapitulation

Recapitulation

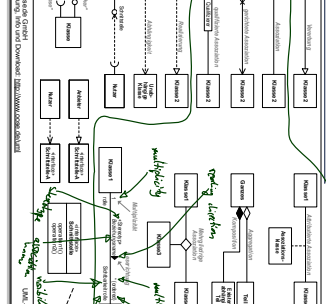

- We extended the type system for
 - casts (requires change of I) and
 - visibility (no change of I).
 - **Later:** navigability of associations.
- Good:** well-typedness is decidable for these type systems. That is, we can have automatic tools that check, whether OCL expressions in a model are well-typed.

Associations' Syntax

- an association has
 - a name,
 - a reading direction, and of the system
 - at least two ends.
 - Each end has
 - a role name,
 - a multiplicity,
 - a set of properties, such as unique, ordered, etc
 - a qualifier, (or not and how)
 - a visibility,
 - a navigability,
 - and possibly a diamond (weak)
- Warning:** places in the signature to represent the information from the picture.

- **Only** for the course of Lectures 07/08 we assume that each attribute in V
 - either is $(\nu : \tau, \xi, \text{exp}, \alpha, P_1)$ with $\tau \in \mathcal{D}$ (as before)
 - or is an association of the form

$$\langle r : (\text{role}_1 : C_1, \mu_1, P_1, \xi_1, \nu_1, \alpha_1), \dots \rangle$$
- where
- $n \geq 2$ (at least two ends),
 - r, role_i are just names, $C_i \in \mathcal{C}$, $1 \leq i \leq n$,
 - the multiplicity μ_i is an expression of the form

$$\mu_i ::= * | N | N..M | N..* | A_i \mu_i$$
 - P_i is a set of properties (as before),
 - $\xi_i \in \{+, -, \#, \sim\}$ (as before),
 - $\nu_i \in \{X, \sim, \rightarrow\}$ is the navigability,
 - $\alpha_i \in B$ is the ownership.

- **Only** for the course of Lectures 07/08 we assume that each attribute in V
 - either is $(\nu : \tau, \xi, \text{exp}, \alpha, P_1)$ with $\tau \in \mathcal{D}$ (as before)
 - or is an association of the form

$$\langle r : (\text{role}_1 : C_1, \mu_1, P_1, \xi_1, \nu_1, \alpha_1), \dots \rangle$$
- Alternative syntax for multiplicities
- $N..M$ \mathcal{Q} $\mu ::= N..M | N..* | \mu_1 \mu_2$ $(N, M \in \mathbb{N} \cup \{*\})$
- and define ξ and N as abbreviations, e.g. $0..*$ for $1..*$
- Note: N could abbreviate $0..N$, $1..N$, or $N..N$. We use last one.
- r, role_i are just names, $C_i \in \mathcal{C}$, $1 \leq i \leq n$,
 - the multiplicity μ_i is an expression of the form

$$\mu_i ::= * | N | N..M | N..* | \mu_1 \mu_2$$
 - P_i is a set of properties (as before),
 - $\xi_i \in \{+, -, \#, \sim\}$ (as before),
 - $\nu_i \in \{X, \sim, \rightarrow\}$ is the navigability,
 - $\alpha_i \in B$ is the ownership.

Also only for the course of 98 lectures 09-109

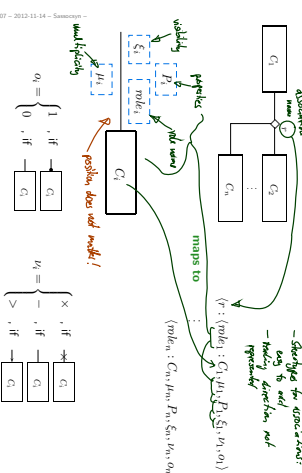

- we only consider basic type attributes to "belong" to a class (to appear in $atr(C)$).
- associations are not "owned" by a particular class (do not appear in $atr(C)$), but live on their own.

Formally, we only call

$$(\mathcal{S}, \mathcal{E}, V, atr)$$

a signature (extended for associations) if

$$atr : \mathcal{C} \rightarrow 2^{(\text{Attr} \cup \text{EAttr})}$$

What If Things Are Missing?

Most components of associations or association end may be omitted for instance [7, 17], Section 6.4.2, proposes the following rules:

- Name: Use

$$A(C_1, \dots, C_n)$$

if the name is missing.

Example:

- Reading Direction: no default.

- Role Name: use the class name at that end in lower-case letters

Example:

- Other convention (used e.g. by modelling tool Rhapsody)

What If Things Are Missing?

0..*

- Multiplicity: 1. In my opinion, it's safer to assume 0, 1 or * if there are no fixed, written, agreed conventions ("respect the worst").

- Properties: \emptyset (Last: Simple)

- Visibility: public

- Visibility and Ownership: not so easy. [7, 43]

"Various options may be chosen for showing navigation arrows on a diagram. In practice, it is often convenient to suppress some of the arrows and crosses and just show exceptional situations:

- Show all arrows and x's. Navigation and its absence are made completely explicit.
- Suppress all arrows and x's. No inference can be drawn about navigation. This is similar to any situation in which information is suppressed from a view.
- Suppress arrows for associations with one-way navigability, and show arrows only for associations with one-way navigability.
- In this case, the two-way navigability cannot be distinguished from situations where there is no navigation at all; however, the latter case occurs rarely in practice.

Signature:

$$\mathcal{S} = \{(m_1, \{C, D\}), \dots\}$$

$\langle r \in C, D, w \rangle$ like
 $\langle r \in C, D, w \rangle$ like
 $\langle r \in D, 0..*, \text{simple} \rangle$ like
 $\{C, D\}$ why does the asterisk live?
 $D, 1, \{x\}$

What If Things Are Missing...

...is causing so much trouble (e.g. leading to misunderstanding), why does the standard say "In practice, it is often convenient..."?

Is it a good idea to trade convenience for precision/ambiguity?

It depends.

- Convenience as such is a legitimate goal.
- In UML-As-Sketch mode, precision "doesn't matter", so convenience (for writer) can even be a primary goal.
- In UML-As-Blueprint mode, precision is the primary goal.

And misunderstandings are in most cases annoying.
 But (even in UML-As-Blueprint mode) if an association in your model has multiplicity * at both ends, it's probably a good idea not to write all these *'s. So tell the reader about it and leave out the *'s.
