

Software Design, Modelling and Analysis in UML

Lecture 22: Meta-Modelling, Inheritance III

2013-02-06

Prof. Dr. Andreas Podelski, **Dr. Bernd Westphal**

Albert-Ludwigs-Universität Freiburg, Germany

Contents & Goals

Last Lecture:

- Inheritance in UML: desired semantics

This Lecture:

- **Educational Objectives:** Capabilities for following tasks/questions.
 - What's the Liskov Substitution Principle?
 - What is late/early binding?
 - What is the subset, what the uplink semantics of inheritance?
 - What's the effect of inheritance on LSCs, State Machines, System States?
 - What's the idea of Meta-Modelling?
- **Content:**
 - Meta-Modelling
 - Two approaches to obtain desired semantics

Meta-Modelling: Idea and Example

Meta-Modelling: Why and What

- **Meta-Modelling** is one major prerequisite for understanding
 - the standard documents [OMG, 2007a, OMG, 2007b], and
 - the MDA ideas of the OMG.
- The idea is **simple**:
 - if a **modelling language** is about modelling **things**,
 - and if UML models are and comprise **things**,
 - then why not **model** those in a modelling language?
- In other words:

Why not have a model \mathcal{M}_U such that

- the set of legal instances of \mathcal{M}_U

is

- the set of well-formed (!) UML models.

Meta-Modelling: Example

- For example, let's consider a class.
- A **class** has (on a superficial level)
 - a **name**,
 - any number of **attributes**,
 - any number of **behavioural features**.

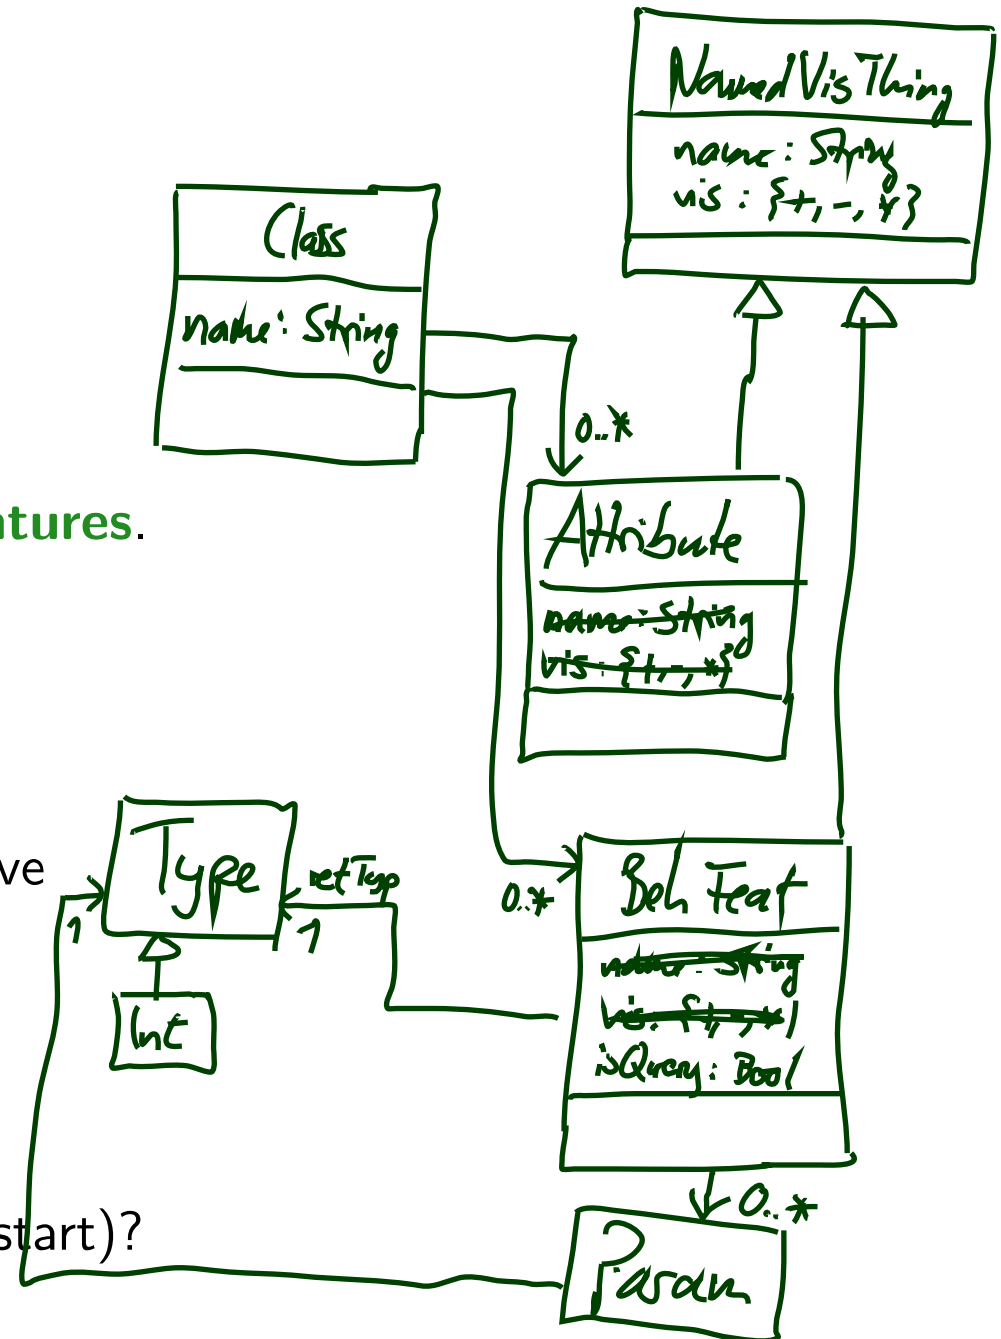

Each of the latter two has

- a **name** and
- a **visibility**.

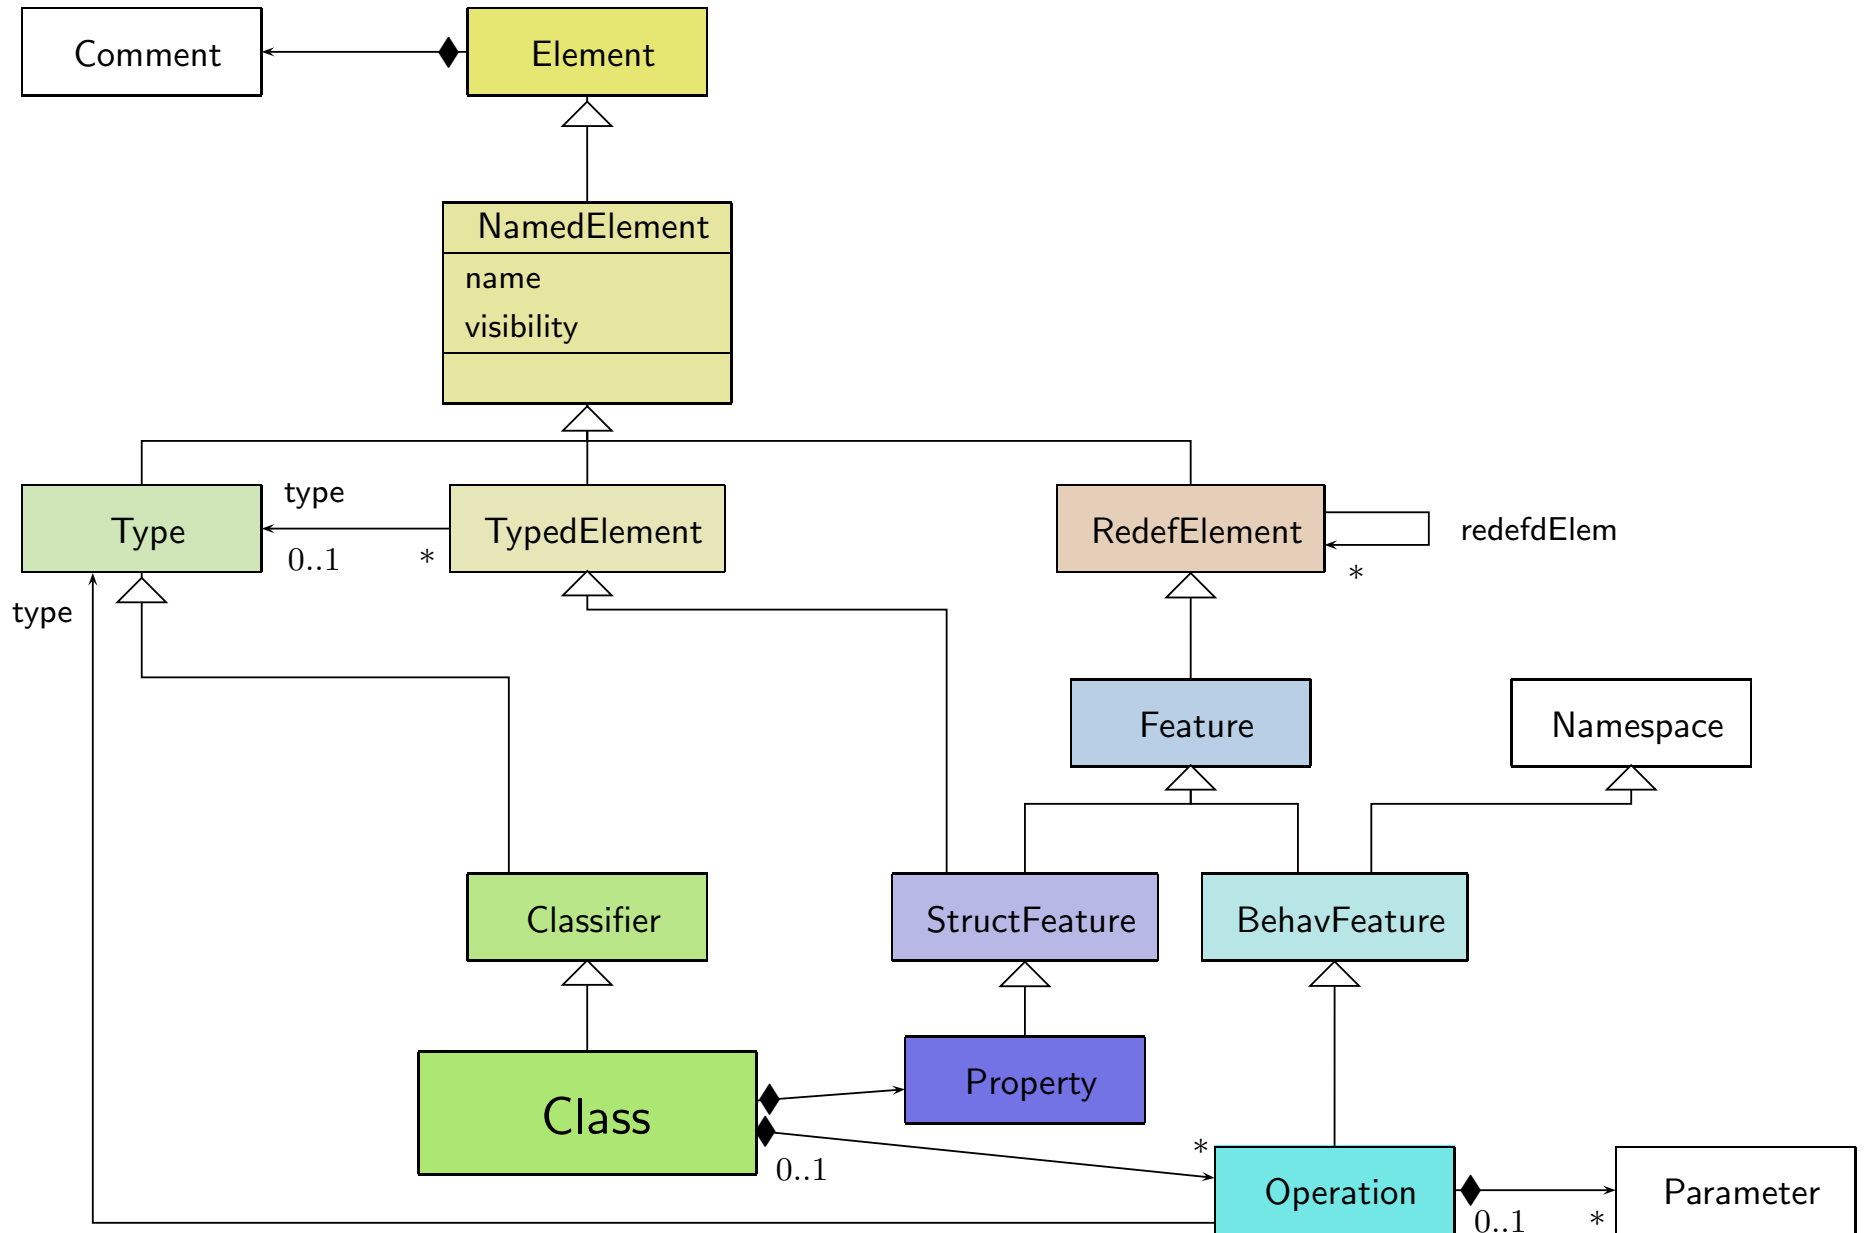

Behavioural features in addition have

- a boolean attribute **isQuery**,
- any number of parameters,
- a return type.

- Can we model this (in UML, for a start)?

UML Meta-Model: Extract

Interesting: Declaration/Definition [OMG, 2007b, 424]

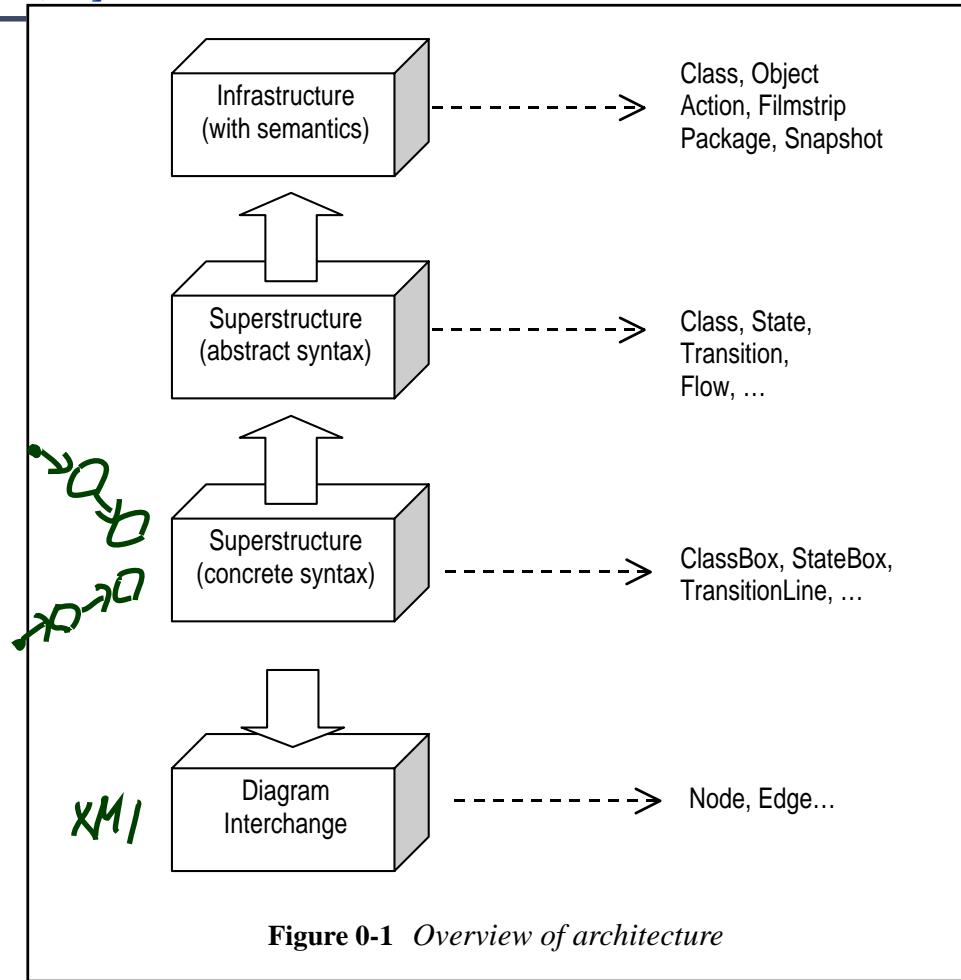

Figure 13.6 - Common Behavior

UML Architecture [OMG, 2003, 8]

- Meta-modelling has already been used for UML 1.x.
- For UML 2.0, the request for proposals (RFP) asked for a separation of concerns:
Infrastructure and **Superstructure**.
- **One reason:** sharing with MOF (see later) and, e.g., CWM.

UML Superstructure Packages [OMG, 2007a, 15]

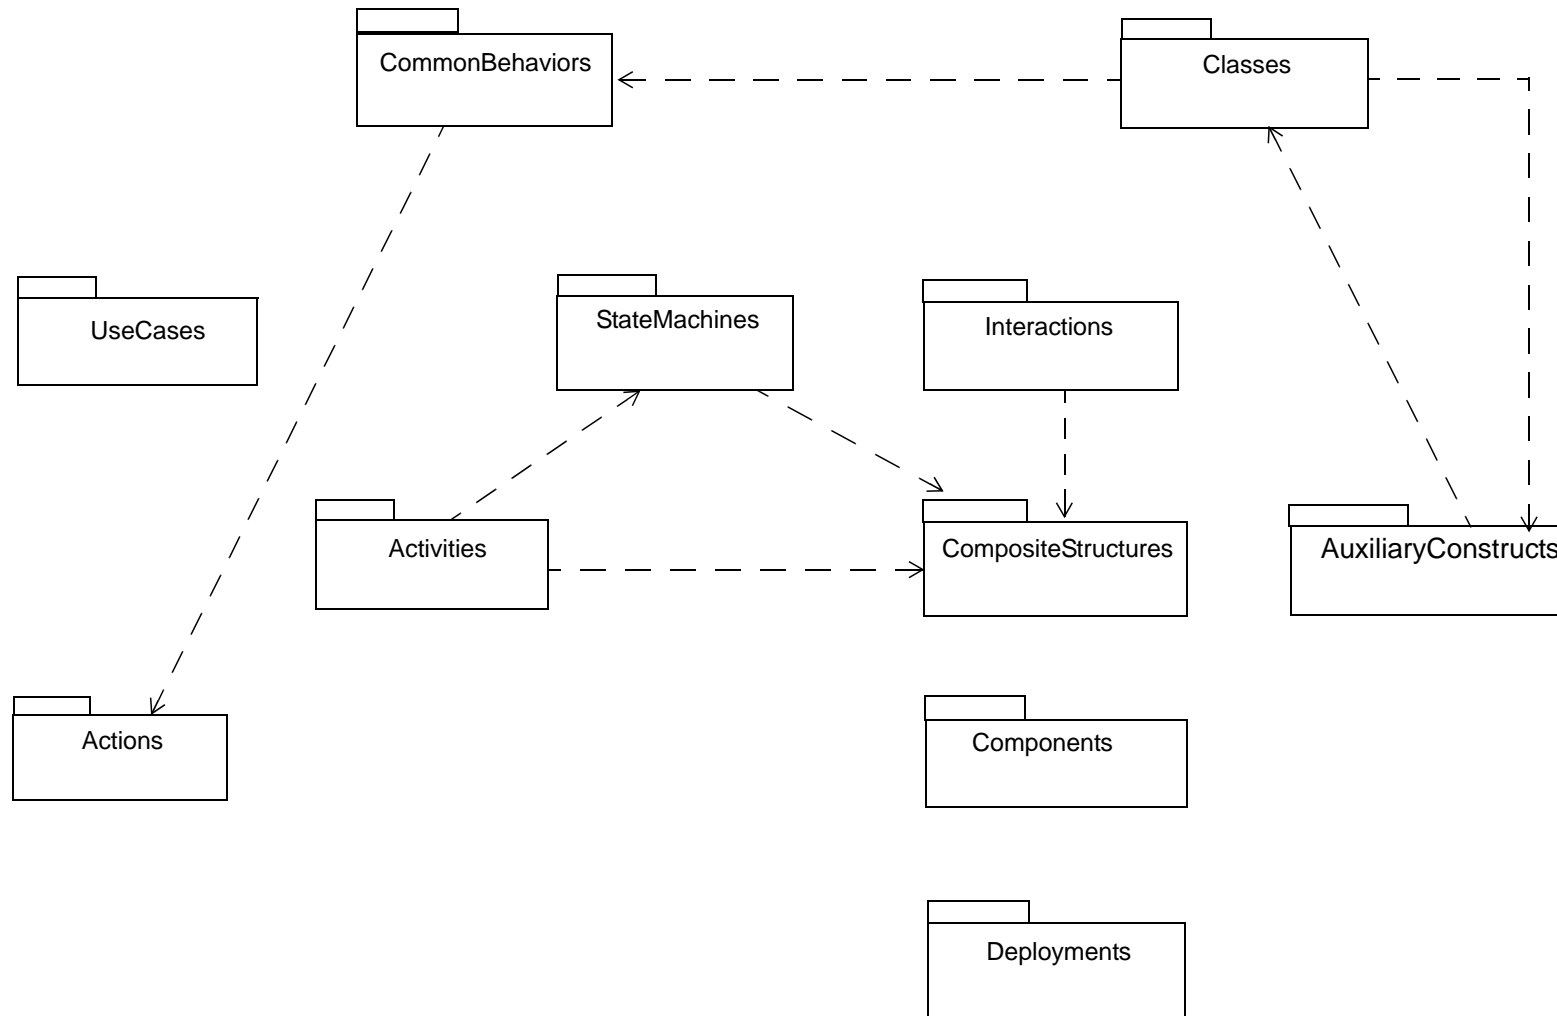

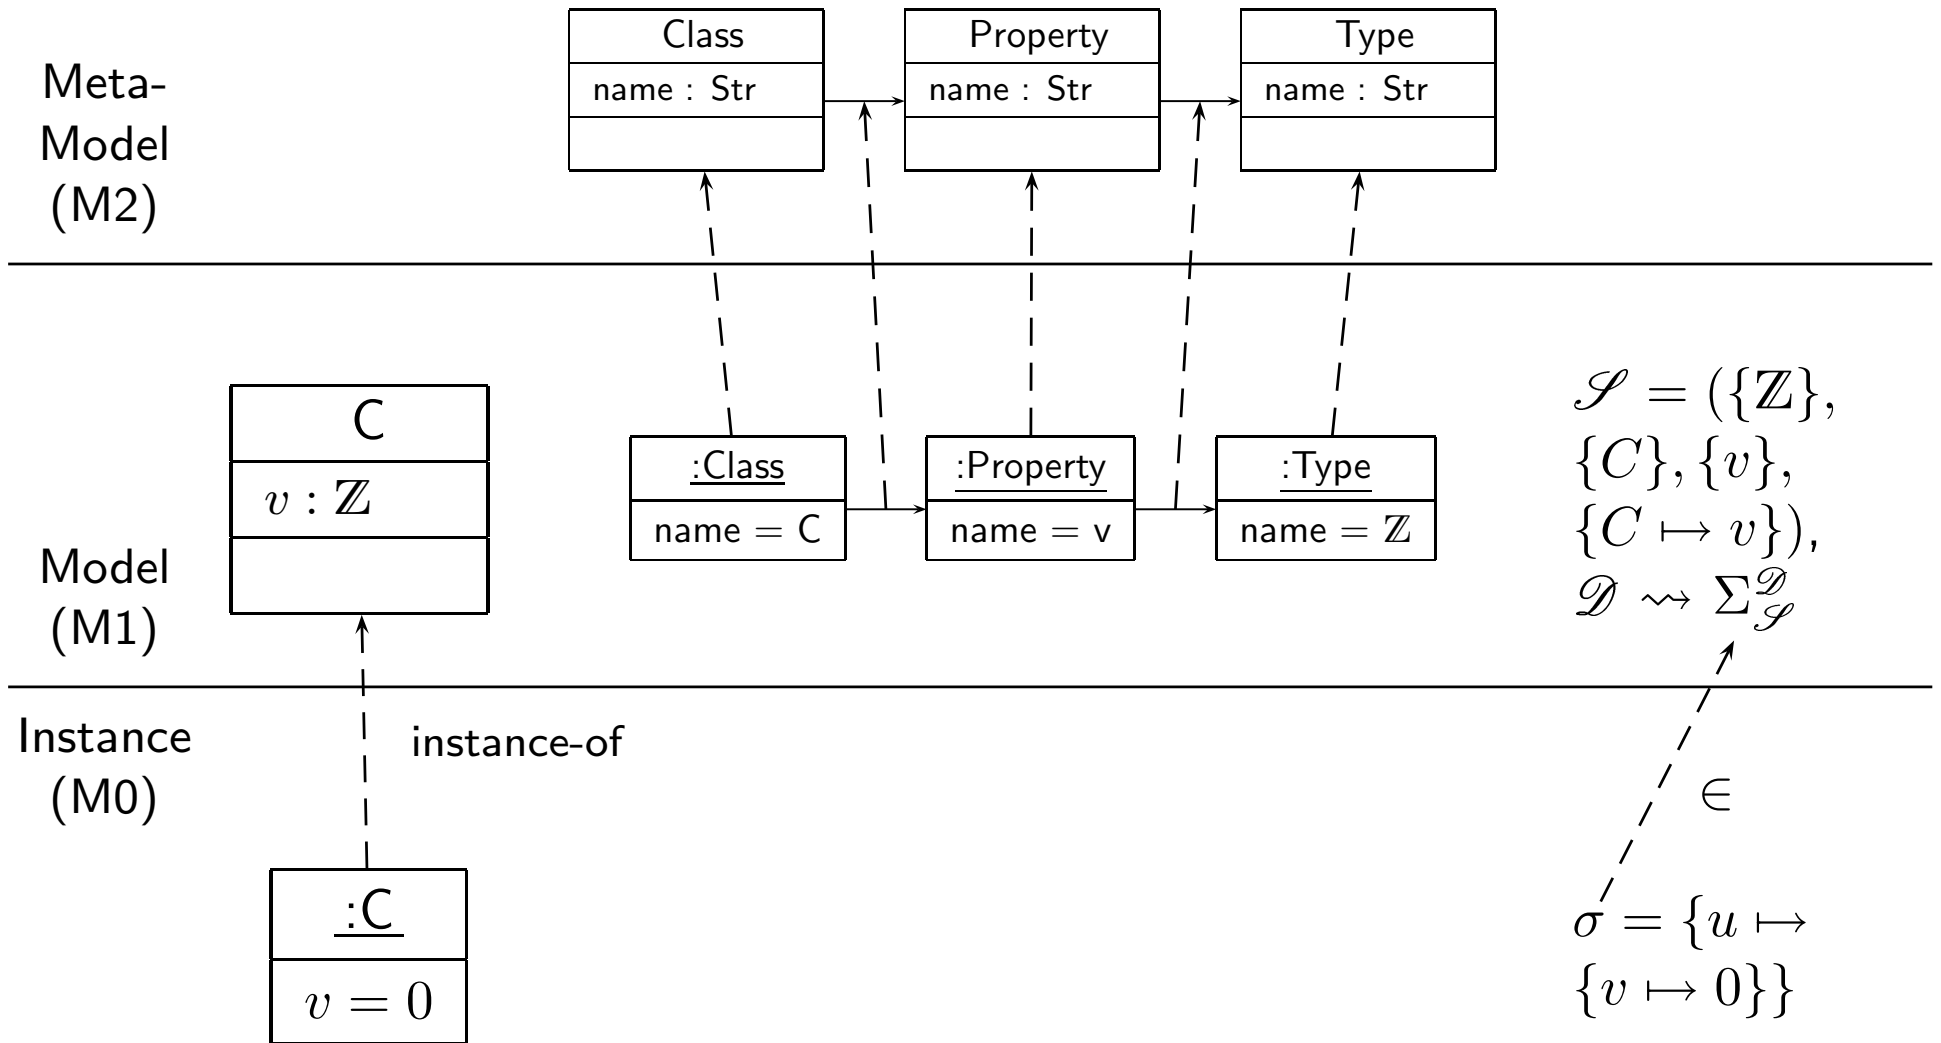

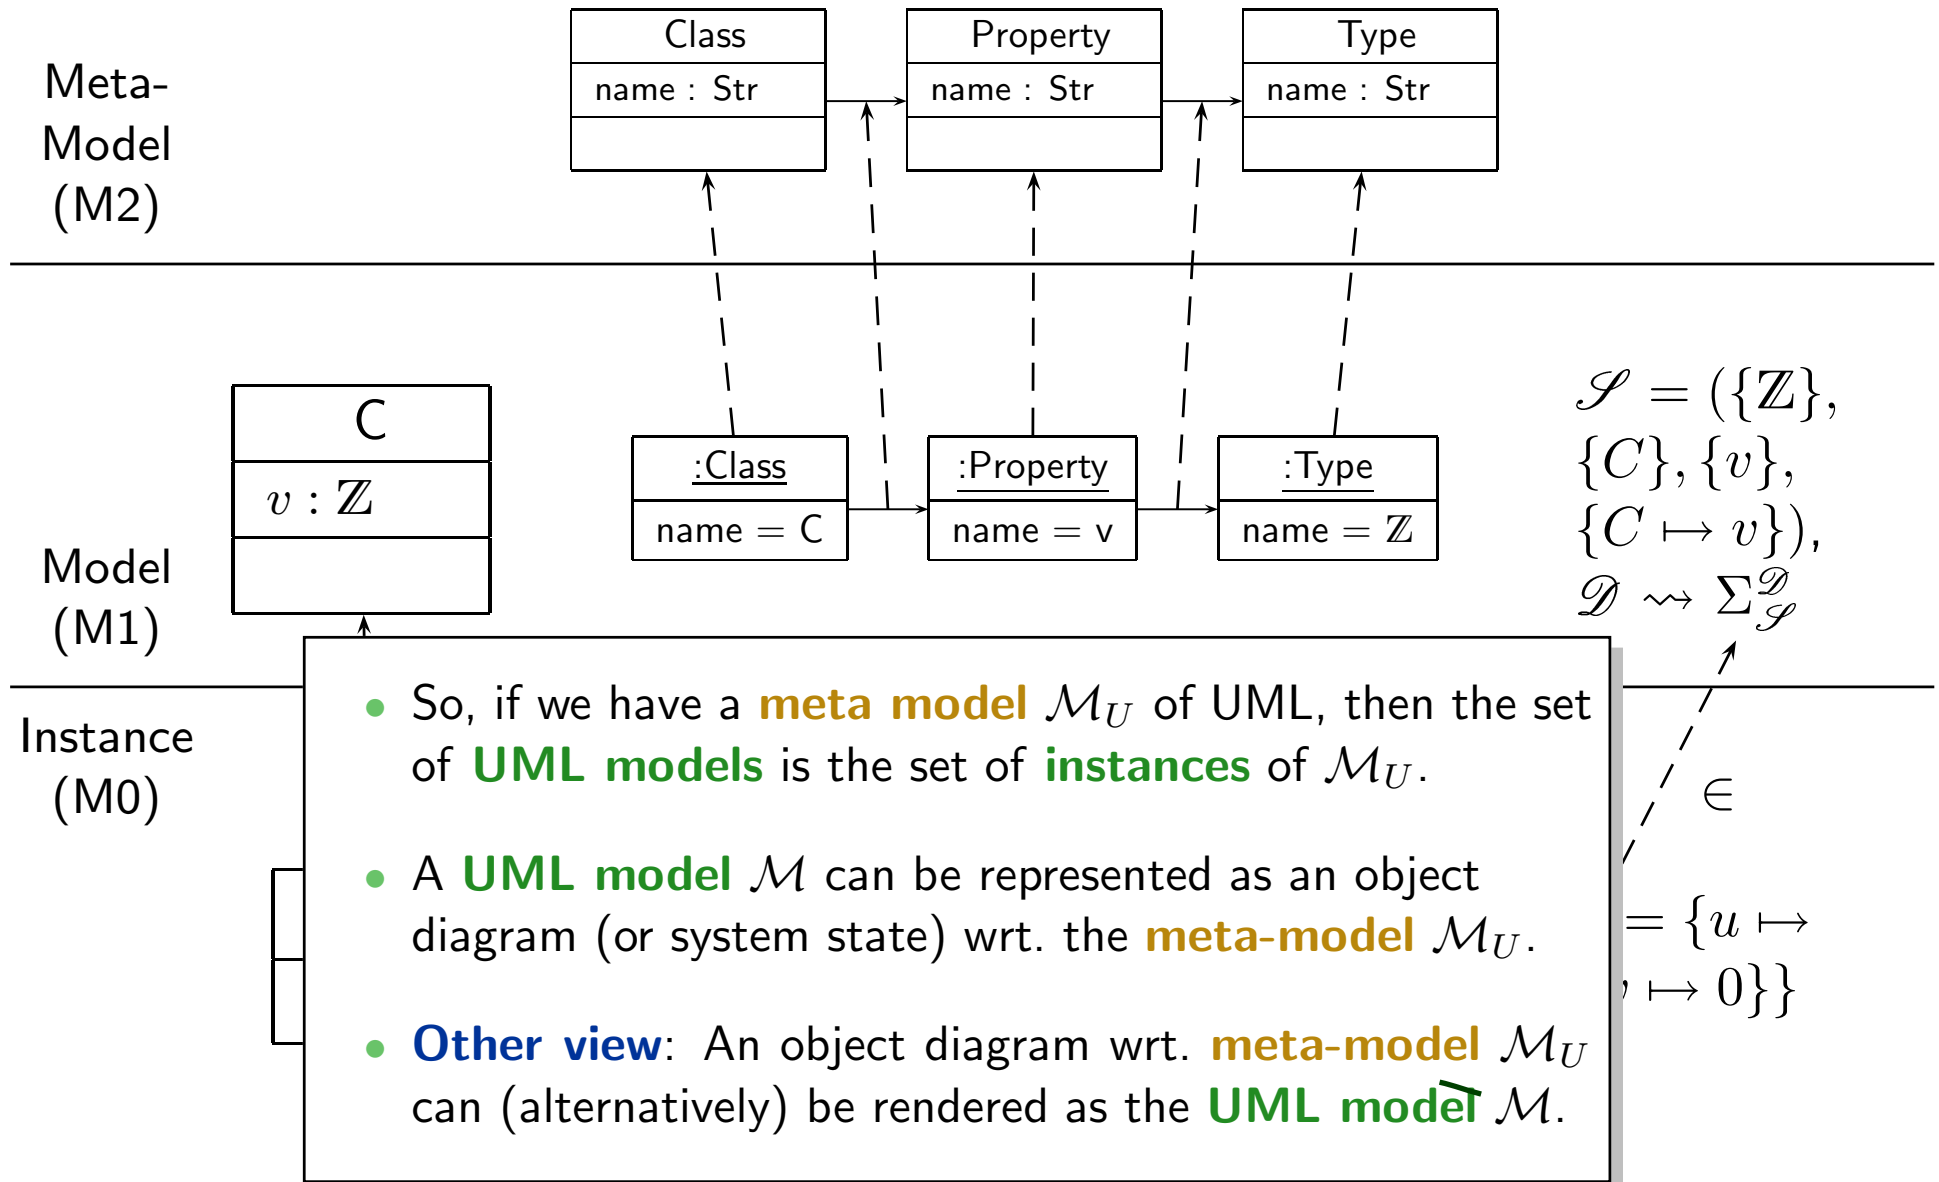

Figure 7.5 - The top-level package structure of the UML 2.1.1 Superstructure

Meta-Modelling: Principle

Modelling vs. Meta-Modelling

Modelling vs. Meta-Modelling

Well-Formedness as Constraints in the Meta-Model

- The set of **well-formed UML models** can be defined as the set of object diagrams satisfying all constraints of the **meta-model**.

For example,

“[2] Generalization hierarchies must be directed and acyclical. A classifier cannot be both a transitively general and transitively specific classifier of the same classifier.

not self . allParents() -> includes(self)” [OMG, 2007b, 53]

- The other way round:

Given a **UML model** \mathcal{M} , unfold it into an object diagram O_1 wrt. \mathcal{M}_U .

If O_1 is a **valid** object diagram of \mathcal{M}_U (i.e. satisfies all invariants from $Inv(\mathcal{M}_U)$), then \mathcal{M} is a well-formed UML model.

That is, if we have an object diagram **validity checker** for of the meta-modelling language, then we have a **well-formedness checker** for UML models.

7.3.8 Classifier (from Kernel, Dependencies, PowerTypes)

A classifier is a classification of instances, it describes a set of instances that have features in common.

Generalizations

- “Namespace (from Kernel)” on page 99
- “RedefinableElement (from Kernel)” on page 130
- “Type (from Kernel)” on page 135

Description

A classifier is a namespace whose members can include features. Classifier is an abstract metaclass.

A classifier is a type and can own generalizations, thereby making it possible to define generalization relationships to other classifiers. A classifier can specify a generalization hierarchy by referencing its general classifiers.

A classifier is a redefinable element, meaning that it is possible to redefine nested classifiers.

Attributes

- isAbstract: Boolean
If *true*, the Classifier does not provide a complete declaration and can typically not be instantiated. An abstract classifier is intended to be used by other classifiers (e.g., as the target of general metarelations or generalization relationships). Default value is *false*.

Associations

- /attribute: Property [*]
Refers to all of the Properties that are direct (i.e., not inherited or imported) attributes of the classifier. Subsets *Classifier::feature* and is a derived union.
- /feature : Feature [*]
Specifies each feature defined in the classifier. Subsets *Namespace::member*. This is a derived union.
- /general : Classifier[*]
Specifies the general Classifiers for this Classifier. This is derived.

Reading the Standard Cont'd

```

A classifier is a

Attributes

- isAbstract: Boolean
If true, the classifier is abstract.

Associations

- /attribute : P
Refers to the Classifier.
- /feature : F
Specifies the Feature.
- /general : C
Specifies the Classifier.

- generalization: Generalization[*]
Specifies the Generalization relationships for this Classifier. These Generalizations navigate to more general classifiers in the generalization hierarchy. Subsets *Element::ownedElement*
- /inheritedMember: NamedElement[*]
Specifies all elements inherited by this classifier from the general classifiers. Subsets *Namespace::member*. This is derived.
- redefinedClassifier: Classifier [*]
References the Classifiers that are redefined by this Classifier. Subsets *RedefinableElement::redefinedElement*

Package Dependencies

- substitution : Substitution
References the substitutions that are owned by this Classifier. Subsets *Element::ownedElement* and *NamedElement::clientDependency*.

Package PowerTypes

- powertypeExtent : GeneralizationSet
Designates the GeneralizationSet of which the associated Classifier is a power type.

Constraints

- [1] The general classifiers are the classifiers referenced by the generalization relationships.
`general = self.parents()`
- [2] Generalization hierarchies must be directed and acyclical. A classifier cannot be both a transitively general and transitively specific classifier of the same classifier.
`not self.allParents()->includes(self)`
- [3] A classifier may only specialize classifiers of a valid type.
`self.parents()->forAll(c | self.maySpecializeType(c))`
- [4] The inheritedMember association is derived by inheriting the inheritable members of the parents.
`self.inheritedMember->includesAll(self.inherit(self.parents()->collect(p | p.inheritableMembers(self)))`

Package PowerTypes

- [5] The Classifier that maps to a GeneralizationSet may neither be a specific nor a general Classifier in any of the Generalization relationships defined for that GeneralizationSet. In other words, a power type may not be an instance of itself nor may its instances also be its subclasses.

Additional Operations

- [1] The query allFeatures() gives all of the features in the namespace of the classifier. In general, through mechanisms such as inheritance, this will be a larger set than feature.
`Classifier::allFeatures(): Set(Feature);`
`allFeatures = member->select(oclsKindOf(Feature))`
- [2] The query parents() gives all of the immediate ancestors of a generalized Classifier.
`Classifier::parents(): Set(Classifier);`
`parents = generalization.general`

Constraints

- [1] The generalization relationship is transitive.
- [2] Generalization is transitive.
- [3] A classifier is not self-generalized.
- [4] The inheritance relationship is transitive.

Package Power

- [5] The Classifier is not generalized by itself nor by its ancestors.

Additional Operations

- [1] The query allParents() gives all of the direct and indirect ancestors of a generalized Classifier.
- [2] The query inheritableMembers() gives all of the members of a classifier that may be inherited in one of its descendants, subject to whatever visibility restrictions apply.
- [3] The query hasVisibilityOf() determines whether a named element is visible in the classifier. By default all are visible. It is only called when the argument is something owned by a parent.
- [4] The query conformsTo() gives true for a classifier that defines a type that conforms to another. This is used, for example, in the specification of signature conformance for operations.
- [5] The query inherit() defines how to inherit a set of elements. Here the operation is defined to inherit them all. It is intended to be redefined in circumstances where inheritance is affected by redefinition.
- [6] The query maySpecializeType() determines whether this classifier may have a generalization relationship to classifiers of the specified type. By default a classifier may specialize classifiers of the same or a more general type. It is intended to be redefined by classifiers that have different specialization constraints.

```

Classifier::allParents(): Set(Classifier);
allParents = self.parents()->union(self.parents()->collect(p | p.allParents()))

```

```

Classifier::inheritableMembers(c: Classifier): Set(NamedElement);
pre: c.allParents()->includes(self)
inheritableMembers = member->select(m | c.hasVisibilityOf(m))

```

```

Classifier::hasVisibilityOf(n: NamedElement) : Boolean;
pre: self.allParents()->collect(c | c.member)->includes(n)
if (self.inheritedMember->includes(n)) then
  hasVisibilityOf = (n.visibility <> #private)
else
  hasVisibilityOf = true

```

```

Classifier::conformsTo(other: Classifier): Boolean;
conformsTo = (self=other) or (self.allParents()->includes(other))

```

```

Classifier::inherit(inhs: Set(NamedElement)): Set(NamedElement);
inherit = inhs

```

```

Classifier::maySpecializeType(c: Classifier) : Boolean;
maySpecializeType = self.oclIsKindOf(c.oclType)

```

Semantics

A classifier is a classification of instances according to their features.

A Classifier may participate in generalization relationships with other Classifiers. An instance of a specific Classifier is also an (indirect) instance of each of the general Classifiers. Therefore, features specified for instances of the general classifier are implicitly specified for instances of the specific classifier. Any constraint applying to instances of the general classifier also applies to instances of the specific classifier.

The specific semantics of how generalization affects each concrete subtype of Classifier varies. All instances of a classifier have values corresponding to the classifier's attributes.

A Classifier defines a type. Type conformance between generalizable Classifiers is defined so that a Classifier conforms to itself and to all of its ancestors in the generalization hierarchy.

```

The notion of power type was inspired by the notion of power set. A power set is defined as a set whose instances are subsets. In essence, then, a power type is a class whose instances are subclasses. The powertypeExtent association relates a Classifier with a set of generalizations that a) have a common specific Classifier, and b) represent a collection of subsets for that class.

Semantic Variation Points

The precise lifecycle semantics of aggregation is a semantic variation point.

Notation

Classifier is an abstract model element, and so properly speaking has no notation. It is nevertheless convenient to define in one place a default notation available for any concrete subclass of Classifier for which this notation is suitable. The default notation for a classifier is a solid-outline rectangle containing the classifier’s name, and optionally with compartments separated by horizontal lines containing features or other members of the classifier. The specific type of classifier can be shown in guillemets above the name. Some specializations of Classifier have their own distinct notations.

The name of an abstract Classifier is shown in italics.

An attribute can be shown as a text string. The format of this string is specified in the Notation sub clause of “Property (from Kernel, AssociationClasses)” on page 123.

Presentation Options

Any compartment may be suppressed. A separator line is not drawn for a suppressed compartment. If a compartment is suppressed, no inference can be drawn about the presence or absence of elements in it. Compartment names can be used to remove ambiguity, if necessary.

An abstract Classifier can be shown using the keyword {abstract} after or below the name of the Classifier.

The type, visibility, default, multiplicity, property string may be suppressed from being displayed, even if there are values in the model.

The individual properties of an attribute can be shown in columns rather than as a continuous string.

Style Guidelines

- Attribute names typically begin with a lowercase letter. Multi-word names are often formed by concatenating the words and using lowercase for all letters except for upcasing the first letter of each word but the first.
- Center the name of the classifier in boldface.
- Center keyword (including stereotype names) in plain face within guillemets above the classifier name.
- For those languages that distinguish between uppercase and lowercase characters, capitalize names (i.e, begin them with an uppercase character).
- Left justify attributes and operations in plain face.
- Begin attribute and operation names with a lowercase letter.
- Show full attributes and operations when needed and suppress them in other contexts or references.

Examples

Figure 7.30 - Examples of attributes

The attributes in Figure 7.30 are explained below.

- ClassA::name is an attribute with type String.
- ClassA::shape is an attribute with type Rectangle.
- ClassA::size is a public attribute of type Integer with multiplicity 0..1.
- ClassA::area is a derived attribute with type Integer. It is marked as read-only.
- ClassA::height is an attribute of type Integer with a default initial value of 5.
- ClassA::width is an attribute of type Integer.
- ClassB::id is an attribute that redefines ClassA::name.
- ClassB::shape is an attribute that redefines ClassA::shape. It has type Square, a specialization of Rectangle.
- ClassB::height is an attribute that redefines ClassA::height. It has a default of 7 for ClassB instances that overrides the ClassA default of 5.
- ClassB::width is a derived attribute that redefines ClassA::width, which is not derived.

An attribute may also be shown using association notation, with no adornments at the tail of the arrow as shown in Figure 7.31.

7.3.8 Classifiers

A classifier is a

Generalization

- “Namespaces”
- “Redefinitions”
- “Type (from Kernel)”

Description

A classifier is a
A classifier is a
other classifiers
A classifier is a

Attributes

- isAbstract: Boolean
If true, the classifier is abstract.

Associations

- /attribute: PackageName
Refers to the package of the classifier.
- /feature: FeatureName
Specifies the feature of the classifier.
- /general: ClassifierName
Specifies the general classifier.

- generalizationSet: GeneralizationSet
Specifies the generalization set of the classifier.
- /inheritedModel: Model
Specifies the inherited model of the classifier.
- redefinedClassifier: ClassifierName
Refers to the classifier that is redefined.

Package Dependencies

- substitutionReferencedClassifier: ClassifierName
NamedClassifierName

Package PowerTypes

- powertypeElement: ElementName
DesignatedElementName

Constraints

- [1] The generalizationSet = self
- [2] GeneralizationSet.transitivity = self.allParents
- [3] A classifier is a generalization of self.parents
- [4] The inheritedClassifier = self.inheritedClassifier

Package PowerTypes

- [5] The Classifier is a generalization of itself nor may it be a generalization of itself.

Additional Options

- [1] The query allParents = ClassifierName
- [2] The query parents = generalClassifierName

Package PowerTypes

The notion of power types is used to define subsets. In essence, a Classifier with a power type for that class.

Semantic Variants

The precise life cycle of a Classifier is defined by its name.

Notation

Classifier is an element in one place and a default notation for compartments. A classifier can be named.

The name of an attribute can be (from Kernel, A Classifier conforms to

[6] The query conformsTo = ClassifierName

Presentation Options

- [7] The query to be redefined = ClassifierName
- [8] The query the specifier redefined by = ClassifierName

Figure 7.31 - Annotated Element

Package PowerTypes

For example, a Bank Account Type classifier could have a powertype association with a GeneralizationSet. This GeneralizationSet could then associate with two Generalizations where the class (i.e., general Classifier) Bank Account has two specific subclasses (i.e., Classifiers): Checking Account and Savings Account. Checking Account and Savings Account, then, are instances of the power type: Bank Account Type. In other words, Checking Account and Savings Account are both instances of Bank Account Type, as well as subclasses of Bank Account. (For more explanation and examples, see Examples in the GeneralizationSet sub clause, below.)

7.3.9 Comment (from Kernel)

A comment is a textual annotation that can be attached to a set of elements.

Generalizations

- “Element (from Kernel)” on page 64.

Description

A comment gives the ability to attach various remarks to elements. A comment carries no semantic force, but may contain information that is useful to a modeler.

A comment can be owned by any element.

Attributes

- multiplicitybody: String [0..1]
Specifies a string that is the comment.

Associations

- annotatedElement: Element[*]
References the Element(s) being commented.

Constraints

No additional constraints

Semantics

A Comment adds no semantics to the annotated elements, but may represent information useful to the reader of the model.

Notation

A Comment is shown as a rectangle with the upper right corner bent (this is also known as a “note symbol”). The rectangle contains the body of the Comment. The connection to each annotated element is shown by a separate dashed line.

Presentation Options

The dashed line connecting the note to the annotated element(s) may be suppressed if it is clear from the context, or not important in this diagram.

Meta Object Facility (MOF)

Open Questions...

- Now you've been **"tricked"** again. Twice.
 - We didn't tell what the **modelling language** for meta-modelling is.
 - We didn't tell what the **is-instance-of** relation of this language is.
- **Idea**: have a **minimal object-oriented core** comprising the notions of **class, association, inheritance, etc.** with "self-explaining" semantics.

- This is **Meta Object Facility** (MOF), which (more or less) coincides with UML Infrastructure [OMG, 2007a].

- So: things on meta level

- M0 are object diagrams/system states *(objects/instances of classes in a UML model)*
- M1 are **words of the language UML** *(objects/instances of classes in the UML-meta-model)*
- M2 are **words of the language MOF** *(instances of MOF meta-model)*
- M3 are **words of the language MOF** *:*
- *:*

- One approach:
 - Treat it with **our signature-based theory**
 - This is (in effect) the right direction, but may require new (or extended) signatures for each level.
(For instance, MOF doesn't have a notion of Signal, our signature has.)
- Other approach:
 - Define a **generic, graph based** “is-instance-of” relation.
 - Object diagrams (that **are** graphs) then **are** the system states — not **only graphical representations** of system states.
 - If this works out, good: We can easily experiment with different language designs, e.g. different flavours of UML that immediately have a semantics.
 - Most interesting: also do generic definition of behaviour within a closed modelling setting, but this is clearly still research, e.g. [\[Buschermöhle and Oelerink, 2008\]](#)

Meta-Modelling: (Anticipated) Benefits

Benefits: Overview

- We'll (superficially) look at three aspects:
 - Benefits for **Modelling Tools**.
 - Benefits for **Language Design**.
 - Benefits for **Code Generation and MDA**.

Benefits for Modelling Tools

- The meta-model \mathcal{M}_U of UML **immediately** provides a **data-structure** representation for the abstract syntax (\sim for our signatures).

If we have code generation for UML models, e.g. into Java, then we can immediately represent UML models **in memory** for Java.

(Because each MOF model is in particular a UML model.)

- There exist tools and libraries called **MOF-repositories**, which can generically represent instances of MOF instances (in particular UML models).

And which can often generate specific code to manipulate instances of MOF instances in terms of the MOF instance.

Benefits for Modelling Tools Cont'd

- And not only **in memory**, if we can represent MOF instances in files, we obtain a canonical representation of UML models **in files**, e.g. in XML.
→ XML Metadata Interchange (XMI)
- **Note:** A priori, there is no graphical information in XMI (it is only abstract syntax like our signatures) → OMG Diagram Interchange.
- **Note:** There are slight ambiguities in the XMI standard.
And different tools by different vendors often seem to lie at opposite ends on the scale of interpretation. Which is surely a coincidence.
In some cases, it's possible to fix things with, e.g., XSLT scripts, but full vendor independence is today not given.
Plus XMI compatibility doesn't necessarily refer to Diagram Interchange.
- **To re-iterate:** this is **generic for all** MOF-based modelling languages such as UML, CWM, etc.
And also for **Domain Specific Languages** which don't even exist yet.

Benefits: Overview

- We'll (superficially) look at three aspects:
 - Benefits for **Modelling Tools**. ✓
 - Benefits for **Language Design**.
 - Benefits for **Code Generation and MDA**.

Benefits for Language Design

- Recall: we said that code-generators are possible “readers” of stereotypes.
- For example, (heavily simplifying) we could
 - introduce the stereotypes **Button**, **Toolbar**, ...
 - for convenience, instruct the modelling tool to use special pictures for stereotypes — in the meta-data (the abstract syntax), the stereotypes are clearly present.
 - instruct the code-generator to automatically add inheritance from `Gtk::Button`, `Gtk::Toolbar`, etc. **corresponding** to the stereotype.

Et voilà: we can model Gtk-GUIs and generate code for them.

- Another view:
 - UML with these stereotypes **is a new modelling language**: Gtk-UML.
 - Which lives on the same meta-level as UML (M2).
 - It’s a **Domain Specific Modelling Language** (DSL).

One mechanism to define DSLs (based on UML, and “within” UML): **Profiles**.

Benefits for Language Design Cont'd

- For each DSL defined by a Profile, we immediately have
 - in memory representations,
 - modelling tools,
 - file representations.
- **Note:** here, the **semantics** of the stereotypes (and thus the language of Gtk-UML) **lies in the code-generator**.

That's the first "reader" that understands these special stereotypes.
(And that's what's meant in the standard when they're talking about giving stereotypes semantics).

- One can also impose additional well-formedness rules, for instance that certain components shall all implement a certain interface (and thus have certain methods available). (Cf. [\[Stahl and Völter, 2005\]](#).)

Benefits for Language Design Cont'd

- One step further:
 - Nobody hinders us to obtain a model of UML (written in MOF),
 - throw out parts unnecessary for our purposes,
 - add (= integrate into the existing hierarchy) more adequate new constructs, for instance, **contracts** or something more close to hardware as **interrupt** or **sensor** or **driver**,
 - and maybe also stereotypes.
- a new language standing next to UML, CWM, etc.
- Drawback: the resulting language is not necessarily UML any more, so we **can't use** proven UML modelling tools.
 - But we can use all tools for MOF (or MOF-like things).
For instance, Eclipse EMF/GMF/GEF.

Benefits: Overview

- We'll (superficially) look at three aspects:
 - Benefits for **Modelling Tools**. ✓
 - Benefits for **Language Design**. ✓
 - Benefits for **Code Generation and MDA**.

Benefits for Model (to Model) Transformation

- There are manifold applications for model-to-model transformations:
 - For instance, tool support for **re-factorings**, like moving common attributes upwards the inheritance hierarchy.

This can now be defined as **graph-rewriting** rules on the level of MOF.

The graph to be rewritten is the UML model

- Similarly, one could transform a **Gtk-UML** model into a **UML model**, where the inheritance from classes like `Gtk::Button` is made explicit:

The transformation would add this class `Gtk::Button` and the inheritance relation and remove the stereotype.

- Similarly, one could have a **GUI-UML** model transformed into a **Gtk-UML** model, or a Qt-UML model.

The former a PIM (Platform Independent Model), the latter a PSM (Platform Specific Model) — cf. MDA.

Special Case: Code Generation

- Recall that we said that, e.g. Java code, can also be seen as a model. So code-generation is a **special case** of model-to-model transformation; only the destination looks quite different.
- **Note:** Code generation needn't be as expensive as buying a modelling tool with full fledged code generation.
 - If we have the UML model (or the DSL model) given as an XML file, code generation can be **as simple as** an XSLT script.

“Can be” in the sense of

“There may be situation where a graphical and abstract representation of something is desired which has a clear and direct mapping to some textual representation.”

In general, code generation can (in colloquial terms) become **arbitrarily difficult**.

Example: Model and XMI

```
<?xml version = '1.0' encoding = 'UTF-8' ?>
<XMI xmi.version = '1.2' xmlns:UML = 'org.omg.xmi.namespace.UML' timestamp = 'Mon Feb 02 18:23:12 CET 2009'>
  <XMI.content>
    <UML:Model xmi.id = '...'>
      <UML:Namespace.ownedElement>
        <UML:Class xmi.id = '...' name = 'SensorA'>
          <UML:ModelElement.stereotype>
            <UML:Stereotype name = 'pt100' />
          </UML:ModelElement.stereotype>
        </UML:Class>
        <UML:Class xmi.id = '...' name = 'ControllerA'>
          <UML:ModelElement.stereotype>
            <UML:Stereotype name = '65C02' />
          </UML:ModelElement.stereotype>
        </UML:Class>
        <UML:Class xmi.id = '...' name = 'UsbA'>
          <UML:ModelElement.stereotype>
            <UML:Stereotype name = 'NET2270' />
          </UML:ModelElement.stereotype>
        </UML:Class>
        <UML:Association xmi.id = '...' name = 'in' >...</UML:Association>
        <UML:Association xmi.id = '...' name = 'out' >...</UML:Association>
      </UML:Namespace.ownedElement>
    </UML:Model>
  </XMI.content>
</XMI>
```

Towards System States

Wanted: a formal representation of “if $C \preceq D$ then D ‘is a’ C ”, that is,

- (i) D has the same attributes and behavioural features as C , and
- (ii) D objects (identities) can replace C objects.

We’ll discuss **two approaches** to semantics:

- **Domain-inclusion** Semantics

- **Uplink** Semantics

some $D.x$ *rewrite* \rightarrow some $D.\text{uplink}.x$

(more **theoretical**)

(more **technical**)

Domain Inclusion Semantics

Domain Inclusion Structure

Let $\mathcal{S} = (\mathcal{I}, \mathcal{C}, V, atr, \mathcal{E}, F, mth, \triangleleft)$ be a signature.

Now a **structure** \mathcal{D}

- [as before] maps types, classes, associations to domains,
- [for completeness] methods to transformers,
- [as before] identities of instances of classes not (transitively) related by generalisation are disjoint,
- [changed] the identities of a super-class comprise all identities of sub-classes, i.e.

$$\forall C \in \mathcal{C} : \mathcal{D}(C) \supseteq \bigcup_{C \triangleleft D} \mathcal{D}(D).$$

Note: the old setting coincides with the special case $\triangleleft = \emptyset$.

Domain Inclusion System States

Now: a **system state** of \mathcal{S} wrt. \mathcal{D} is a **type-consistent** mapping

$$\sigma : \mathcal{D}(\mathcal{C}) \mapsto (V \mapsto (\mathcal{D}(\mathcal{T}) \cup \mathcal{D}(\mathcal{C}_{0,1}) \cup \mathcal{D}(\mathcal{C}_*)))$$

that is, for all $u \in \text{dom}(\sigma) \cap \mathcal{D}(C)$,

- **[as before]** $\sigma(u)(v) \in \mathcal{D}(\tau)$ if $v : \tau$, $\tau \in \mathcal{T}$ or $\tau \in \{C_*, C_{0,1}\}$.
- **[changed]** $\text{dom}(\sigma(u)) = \bigcup_{C_0 \preceq C} \text{atr}(C_0)$,

Example:

$$\begin{aligned} & v \in \mathcal{D}(\mathcal{D}) \\ \text{dom}(\sigma(v)) &= \text{atr}(\mathcal{D}) \cup \text{atr}(C) \\ &= \{D::x, D::y, C::x\} \end{aligned}$$

Note: the old setting still coincides with the special case $\triangleleft = \emptyset$.

Preliminaries: Expression Normalisation

Recall:

- we want to allow, e.g., “context D inv: $\boxed{v} < 0$ ”.
- we assume **fully qualified names**, e.g. $C::v$.

Intuitively, \boxed{v} shall denote the

“**most special more general**” $C::v$ according to \triangleleft .

To keep this out of typing rules, we assume that the following **normalisation** has been applied to all OCL expressions and all actions.

- Given expression v (or f) in **context** of class D , as determined by, e.g.
 - by the (type of the) navigation expression prefix, or
 - by the class, the state-machine where the action occurs belongs to,
 - similar for method bodies,
- **normalise** v to (= replace by) $\underline{C::v}$,
- where C is the **greatest** class wrt. “ \preceq ” such that
 - $C \preceq D$ and $C::v \in atr(C)$.

If no (unique) such class exists, the model is considered **not well-formed**; the expression is ambiguous. Then: explicitly provide the **qualified name**.

OCL Syntax and Typing

- Recall (part of the) OCL syntax and typing: $v, r \in V; C, D \in \mathcal{C}$

$$\begin{aligned} \text{expr} ::= & v(\text{expr}_1) & : \tau_C \rightarrow \tau(v), & \text{if } v : \tau \in \mathcal{I} \\ & | r(\text{expr}_1) & : \tau_C \rightarrow \tau_D, & \text{if } r : D_{0,1} \\ & | r(\text{expr}_1) & : \tau_C \rightarrow \text{Set}(\tau_D), & \text{if } r : D_* \end{aligned}$$

The definition of the semantics remains (textually) **the same**.

More Interesting: Well-Typed-ness

- We want

context D inv : $v < 0$

to be well-typed.

Currently it isn't because

$$v(\text{expr}_1) : \tau_C \rightarrow \tau(v)$$

but $A \vdash \text{self} : \tau_D$.

(Because τ_D and τ_C are still **different types**, although $\text{dom}(\tau_D) \subset \text{dom}(\tau_C)$.)

- So, add a (first) new typing rule

$$\frac{A \vdash \text{expr} : \tau_D}{A \vdash \text{expr} : \tau_C}, \text{ if } C \preceq D. \quad (\text{Inh})$$

Which is correct in the sense that, if ' expr ' is of type τ_D , then we can use it everywhere, where a τ_C is allowed.

The system state is prepared for that.

Well-Typed-ness with Visibility Cont'd

$$\frac{A, D \vdash \text{expr} : \tau_C}{A, D \vdash C::v(\text{expr}) : \tau}, \quad \xi = \cdot + \quad (\text{Pub})$$

$$\frac{A, D \vdash \text{expr} : \tau_C}{A, D \vdash C::v(\text{expr}) : \tau}, \quad \xi = \#, \quad C \leq D \quad (\text{Prot})$$

$$\frac{A, D \vdash \text{expr} : \tau_C}{A, D \vdash C::v(\text{expr}) : \tau}, \quad \xi = -, \quad C = D \quad (\text{Priv})$$

$\langle C::v : \tau, \xi, v_0, P \rangle \in \text{atr}(C)$.

Example:

context/ inv	$(n.)v_1 < 0$	$(n.)v_2 < 0$	$(n.)v_3 < 0$
C			
D			
B			

Satisfying OCL Constraints (Domain Inclusion)

- Let $\mathcal{M} = (\mathcal{CD}, \mathcal{OD}, \mathcal{IM}, \mathcal{I})$ be a UML model, and \mathcal{D} a structure.
- We (**continue to**) say $\mathcal{M} \models \text{expr}$ for context C inv : $\text{expr}_0 \in \text{Inv}(\mathcal{M})$ iff

$$= \text{expr}$$

$$\forall \pi = (\sigma_i, \varepsilon_i)_{i \in \mathbb{N}} \in \llbracket \mathcal{M} \rrbracket \quad \forall i \in \mathbb{N} \quad \forall u \in \text{dom}(\sigma_i) \cap \mathcal{D}(C) :$$

$$I[\text{expr}_0](\sigma_i, \{\text{self} \mapsto u\}) = 1.$$

- \mathcal{M} is (still) consistent if and only if it satisfies all constraints in $\text{Inv}(\mathcal{M})$.

Example:

$$I[\text{self}.x > 0](\sigma, \{\text{self} \mapsto v\})$$

normalisation

$$I[\text{self}.c::x > 0](\sigma, \beta)$$

$$= (\sigma(\beta(\text{self}))(c::x), 0)$$

$\in \mathcal{D}(\mathcal{D}) \cap \mathcal{D}(C)$ because $c::x \in \text{attr}(C)$ and $C \leq D$

Transformers (Domain Inclusion)

- Transformers also remain **the same**, e.g. [VL 12, p. 18]

$$\text{update}(\text{expr}_1, v, \text{expr}_2) : (\sigma, \varepsilon) \mapsto (\sigma', \varepsilon)$$

with

$$\sigma' = \sigma[u \mapsto \sigma(u)[v \mapsto I[\text{expr}_2](\sigma)]]$$

where $u = I[\text{expr}_1](\sigma)$.

Semantics of Method Calls

- **Non late-binding:** clear, by normalisation.
- **Late-binding:**
Construct a **method call** transformer, which is applied to all method calls.

Inheritance and State Machines: Triggers

(20)

- **Wanted:** triggers shall also be sensitive for inherited events, sub-class shall execute super-class' state-machine (unless overridden).

DISPATCH

$$(\sigma, \varepsilon) \xrightarrow[u]{(cons, Snd)} (\sigma', \varepsilon') \text{ if}$$

in (*), we're needing an A-identity,

- $\exists u \in \text{dom}(\sigma) \cap \mathcal{D}(C) \exists u_E \in \mathcal{D}(\mathcal{E}) : u_E \in \text{ready}(\varepsilon, u)$
- u is stable and in state machine state s , i.e. $\sigma(u)(\text{stable}) = 1$ and $\sigma(u)(st) = s$,
- a transition is enabled, i.e.

$$\exists (s, F, \text{expr}, \text{act}, s') \in \rightarrow (SM_C) : F = E \wedge I[\text{expr}](\tilde{\sigma}) = 1$$

where $\tilde{\sigma} = \sigma[u.params_E \mapsto u_e]$.

and

- (σ', ε') results from applying t_{act} to (σ, ε) and removing u_E from the ether, i.e.

$$(\sigma'', \varepsilon') = t_{act}(\tilde{\sigma}, \varepsilon \ominus u_E),$$

$$\sigma' = (\sigma''[u.st \mapsto s', u.stable \mapsto b, u.params_E \mapsto \emptyset])|_{\mathcal{D}(\mathcal{E}) \setminus \{u_E\}}$$

where b **depends**:

- If u becomes stable in s' , then $b = 1$. It **does** become stable if and only if there is no transition **without trigger** enabled for u in (σ', ε') .
- Otherwise $b = 0$.
- Consumption of u_E and the side effects of the action are observed, i.e.

$$cons = \{(u, (E, \sigma(u_E)))\}, Snd = Obs_{t_{act}}(\tilde{\sigma}, \varepsilon \ominus u_E).$$

$u_B \in \mathcal{D}(B)$
 $\{u_B \in \mathcal{D}(A)$
 (by inh.)

this allows dispatch

Domain Inclusion and Interactions

- Similar to satisfaction of OCL expressions above:
 - An instance line stands for all instances of C (exact or inheriting).
 - Satisfaction of event observation has to take inheritance into account, too, so we have to **fix**, e.g.

$$\sigma, cons, Snd \models_{\beta} E_{x,y}^!$$

if and only if

$\beta(x)$ sends an F -event to βy where $E \preceq F$.

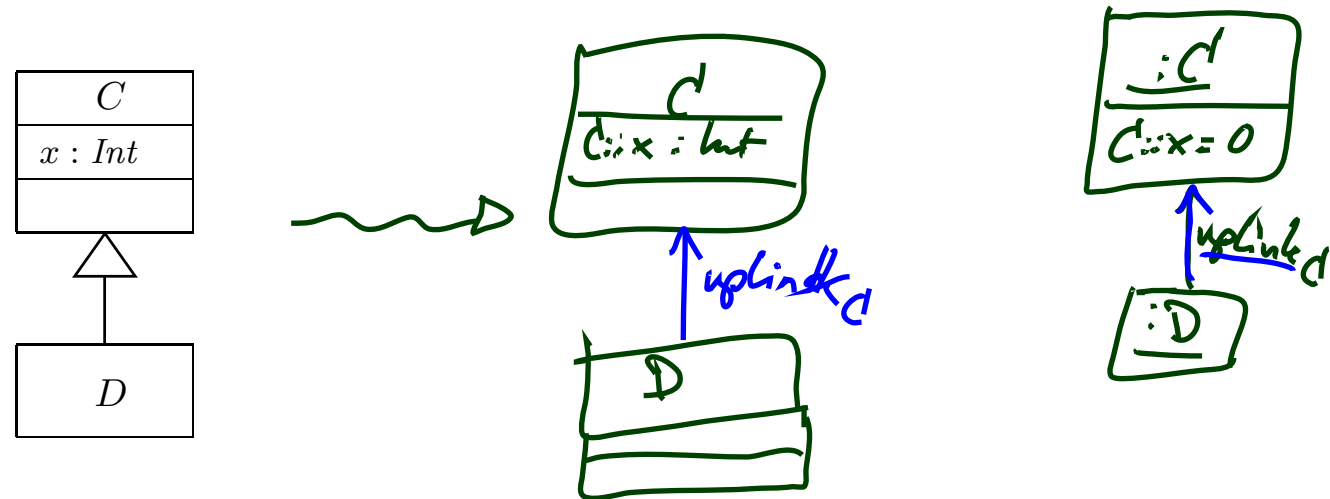

- **Note:** C -instance line also binds to C' -objects.

Uplink Semantics

Uplink Semantics

- **Idea:**

- Continue with the existing definition of **structure**, i.e. disjoint domains for identities.
- Have an **implicit association** from the child to each parent part (similar to the implicit attribute for stability).

- Apply (a different) pre-processing to make appropriate use of that association, e.g. rewrite (C++)

$x = 0;$

in D to

$uplink_C \rightarrow x = 0;$

Pre-Processing for the Uplink Semantics

- For each pair $C \triangleleft D$, extend D by a (fresh) association

$$\text{uplink}_C : C \text{ with } \mu = [1, 1], \xi = +$$

(**Exercise**: public necessary?)

- Given expression v (or f) in the **context** of class D ,
 - let C be the **smallest** class wrt. “ \preceq ” such that
 - $C \preceq D$, and
 - $C::v \in \text{atr}(D)$
 - then there exists (by definition) $C \triangleleft C_1 \triangleleft \dots \triangleleft C_n \triangleleft D$,
 - **normalise** v to (= replace by)

$$\text{uplink}_{C_n} \rightarrow \dots \rightarrow \text{uplink}_{C_1}.C::v$$

- Again: if no (unique) smallest class exists, the model is considered **not well-formed**; the expression is ambiguous.

Uplink Structure, System State, Typing

- Definition of structure remains **unchanged**.
- Definition of system state remains **unchanged**.
- Typing and transformers remain **unchanged** — the preprocessing has put everything in shape.

Satisfying OCL Constraints (Uplink)

- Let $\mathcal{M} = (\mathcal{CD}, \mathcal{OD}, \mathcal{IM}, \mathcal{I})$ be a UML model, and \mathcal{D} a structure.
- We (**continue to**) say

$$\mathcal{M} \models expr$$

for

$$\underbrace{\text{context } C \text{ inv : } expr_0 \in Inv(\mathcal{M})}_{=expr}$$

if and only if

$$\forall \pi = (\sigma_i)_{i \in \mathbb{N}} \in \llbracket \mathcal{M} \rrbracket$$

$$\forall i \in \mathbb{N}$$

$$\forall u \in \text{dom}(\sigma_i) \cap \mathcal{D}(C) :$$

$$I \llbracket expr_0 \rrbracket (\sigma_i, \{self \mapsto u\}) = 1.$$

- \mathcal{M} is (still) consistent if and only if it satisfies all constraints in $Inv(\mathcal{M})$.

Transformers (Uplink)

- What **has to change** is the **create** transformer:

$$\text{create}(C, \text{expr}, v)$$

- Assume, C 's inheritance relations are as follows.

$$C_{1,1} \triangleleft \dots \triangleleft C_{1,n_1} \triangleleft C,$$

...

$$C_{m,1} \triangleleft \dots \triangleleft C_{m,n_m} \triangleleft C.$$

- Then, we have to
 - create one fresh object for each part, e.g.

$$u_{1,1}, \dots, u_{1,n_1}, \dots, u_{m,1}, \dots, u_{m,n_m},$$

- set up the uplinks recursively, e.g.

$$\sigma(u_{1,2})(\text{uplink}_{C_{1,1}}) = u_{1,1}.$$

- And, if we had constructors, be careful with their order.

Late Binding (Uplink)

- Employ something similar to the “mostspec” trick (in a minute!). But the result is typically far from concise.

(Related to OCL’s `isKindOf()` function, and RTTI in C++.)

Domain Inclusion vs. Uplink Semantics

Cast-Transformers

- C c;
- D d;
- **Identity upcast** (C++):
 - C* cp = &d; *// assign address of 'd' to pointer 'cp'*
- **Identity downcast** (C++):
 - D* dp = (D*)cp; *// assign address of 'd' to pointer 'dp'*
- **Value upcast** (C++):
 - *cp = *dp; *// copy attribute values of 'd' into 'c', or,
// more precise, the values of the C-part of 'd'*

Casts in Domain Inclusion and Uplink Semantics

	Domain Inclusion	Uplink
$C^* \text{ cp}$ $= \&d;$	easy: immediately compatible (in underlying system state) because $\&d$ yields an identity from $\mathcal{D}(D) \subset \mathcal{D}(C)$.	easy: By pre-processing, $C^* \text{ cp} = d.\text{uplink}_C$;
$D^* \text{ dp} =$ $(D^*)\text{cp};$	easy: the value of cp is in $\mathcal{D}(D) \cap \mathcal{D}(C)$ because the pointed-to object is a D . Otherwise, error condition.	difficult: we need the identity of the D whose C -slice is denoted by cp . (See next slide.)
$c = d;$	bit difficult: set (for all $C \preceq D$) $(C)(\cdot, \cdot) : \tau_D \times \Sigma \rightarrow \Sigma _{\text{atr}(C)}$ $(u, \sigma) \mapsto \underline{\sigma(u)} _{\text{atr}(C)}$ Note: $\sigma' = \sigma[u_C \mapsto \sigma(u_D)]$ is not type-compatible!	easy: By pre-processing, $c = *(d.\text{uplink}_C)$;

Identity Downcast with Uplink Semantics

- **Recall** (C++): $D\ d; \quad C^* \ cp = \&d; \quad D^* \ dp = (D^*)cp;$
- **Problem**: we need the identity of the D whose C -slice is denoted by cp .
- **One technical solution**:
 - Give up disjointness of domains for **one additional type** comprising all identities, i.e. have

$$\text{all} \in \mathcal{T}, \quad \mathcal{D}(\text{all}) = \bigcup_{C \in \mathcal{C}} \mathcal{D}(C)$$

- In each \preceq -**minimal class** have associations “mostspec” pointing to **most specialised** slices, plus information of which type that slice is.
- Then **downcast** means, depending on the mostspec type (only finitely many possibilities), **going down and then up** as necessary, e.g.

```
switch(mostspec_type){
  case C :
    dp = cp -> mostspec -> uplinkDn -> ... -> uplinkD1 -> uplinkD;
  ...
}
```

Domain Inclusion vs. Uplink Semantics: Differences

- **Note:** The uplink semantics views inheritance as an abbreviation:
 - We only need to touch transformers (create) — and if we had constructors, we didn't even need that (we could encode the recursive construction of the upper slices by a transformation of the existing constructors.)
- **So:**
 - Inheritance **doesn't add** expressive power.
 - And it also **doesn't improve** conciseness **soo dramatically**.

As long as we're “**early binding**”, that is...

Domain Inclusion vs. Uplink Semantics: Motives

- **Exercise:**

What's the point of

- having the **tedious** adjustments of the **theory** if it can be approached **technically**?
- having the **tedious** technical **pre-processing** if it can be approached **cleanly** in the **theory**?
