- 1) **Modularisation**
 - split software into units / components of **manageable size**
 - provide well-defined interface
- 2) **Separation of concerns**
 - each component should be **responsible for a particular area of tasks**
 - group data and operation on that data, functional aspects: functional vs. technical, functionality and interaction
- 3) **Information Hiding**
 - the "need to know principle" / information hiding
 - users (like other people) need not necessarily know the algorithm and/or data structure used in the algorithm
 - and/or data which realises the component's interface
- 4) **Data Encapsulation**
 - other operations to access component data
 - instead of accessing data via variables, files, etc., directly

→ many programming languages and systems offer the means to **realise** some of these principles **technically**, using these means.

- **Similar design: data encapsulation (examples: Java)**
 - Do not access data variables (like `int`), directly, where needed, but encapsulate the data in a component with four operations to access data: write, etc. the data
- **Real-World Example:** Users do not write to bank account directly, only bank clerks do.
- **Information hiding and data encapsulation** – when enforced technically (examples Java) – usually **comes at the price of worse efficiency**.
 - It is more efficient to store a component's data directly
 - It is more efficient to store a component's data in a member of one operation call
 - It is more efficient to store a component's data in a member of one different operation
- **Example:** If a sequence of data items is stored as a single list-like, accessing the data items in reverse order may be more efficient than accessing them in reverse order by position.
 - **Good models** give users the more documentation (e.g., C++ standard library).
 - **Example:** If an information system stores intermediate results at a certain place, it may be tempting to store them in a separate file. This is a good idea, but it is **not** a different container.
 - **Example:** If a mail list is needed to provide context, add a corresponding operation to apply to the interface.

4.) Data Encapsulation

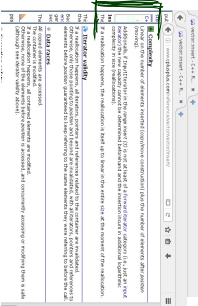

- Similar direction: **data encapsulation** (examples later)
- Do not access data (variables, files, etc.) directly where needed, but encapsulate the data in a component which offers operations to access (read, write, etc.) the data.
- **Real-World Example:** Users do not write to bank accounts directly, only bank staff do.
- **Information hiding and data encapsulation** – when enforced technically (examples later) – usually **come at the price of worse efficiency**.

4.) Data Encapsulation

- **Similar direction: data encapsulation** (examples: list1)
- Do not access data (variables, files, etc.) directly where needed, but encapsulate the data in a component which offers operations to access (read, write, etc.) the data
- **Real-World Example:** Users do not have to bank accounts directly, only bank clerks do.
- **Information hiding and data encapsulation** – when enforced technically (examples: list1) – usually **come at the price of worse efficiency.**

A Classification of Modules (Nagł, 1990)

- **functional module**
 - pure computation which belongs together logically
 - do the same "memory" or state, that is behaviour of object functionally does not depend on "own program evolution"
 - **Example:** mathematical function, transformations
- **data object modules**
 - make an encapsulation of data
 - make an abstraction of data, interface offers operations to manipulate encapsulated data
 - **Example:** module encapsulating global configuration data, databases
- **data type modules**
 - implement a user-defined data type in form of an abstract data type (ADT)
 - make an abstraction of data, interface offers operations to manipulate encapsulated data
 - **Example:** given an object as a memory examples of the data type
- **In an object-oriented design,**
 - data as a data type module,
 - data as an object-oriented design,
 - data as a data type module, component to classes offering only "data methods" or "interfaces" (→ level)
 - functional module, component to classes offering "own example" (raw data as data)

- (i) **information hiding and data encapsulation** not enforced.
- (ii) \rightarrow negative effects when requirements change.
- (iii) **enforcing** information hiding and data encapsulation by modules.
- (iv) **abstract data types**.
- (v) **object oriented** without information hiding and data encapsulation.
- (vi) **object oriented** with information hiding and data encapsulation.

Example: Module 'List of Names'

- **Task:** store list of names in N_x of type list of string.
- **Operators:** (in predefined hierarchy)
 - **insert:** $\text{insert}(x, \text{str})$
 - **pre-condition:** $N_x = n_1, \dots, n_{i-1}, m, n_{i+1}, \dots, n_m, 0 \leq i \leq m, 0 \leq m \leq n_x$
 - **post-condition:** $N_x = n_1, \dots, n_{i-1}, \text{str}, n_{i+1}, \dots, n_m, 0 \leq i \leq m+1, n_x = \text{old}(N_x)$ or $N_x = n_1, \dots, n_{i-1}, \text{str}, n_{i+1}, \dots, n_m, 0 \leq i \leq m, n_x = \text{old}(N_x)$ or $N_x = n_1, \dots, n_{i-1}, \text{str}, n_{i+1}, \dots, n_m, 0 \leq i \leq m, n_x = \text{old}(N_x)$
 - **remove:** $\text{remove}(x, \text{str})$
 - **pre-condition:** $N_x = n_1, \dots, n_{i-1}, n_i, n_{i+1}, \dots, n_m, 0 \leq i \leq m, 0 \leq m \leq n_x$
 - **post-condition:** $N_x = n_1, \dots, n_{i-1}, n_{i+1}, \dots, n_m, 0 \leq i \leq m, n_x \leq i < m$
 - **post-condition:** $N_x = \text{old}(N_x)$ *removed* $= n_i$
 - **post-condition:** $N_x = \text{old}(N_x)$ *not removed* $= n_i$
 - **empty():**

Design Approaches

Software Modelling

Development Approaches

- top-down risk: needed functionally hard to realise on target platform.
- bottom-up risk: lower-level units do not "fit together"
- inside-out risk: user interface needed by customer hard to realise with existing system.
- outside-in risk: elegant system design not reflected nicely in already fixed UI

Architecture Patterns

Introduction

- Over decades of software engineering, many clever, proven and tested designs of solutions for particular problems emerged.

Question: can we generalise, document and re-use these designs?

Goals:

- "Don't re-invent the wheel"
- benefit from "clever" from "proven and tested" and from "solution".

architectural pattern – An architectural pattern expresses a fundamental structural organisation schema for software systems. It specifies their responsibilities, and includes rules and guidelines for organizing the relationships between them.

Buchanan et al. (1994)

23/70

Introduction Cont'd

architectural pattern: An architectural pattern expresses a fundamental structural organisation schema for software systems. It specifies their responsibilities, and includes rules and guidelines for organizing the relationships between them.

Buchanan et al. (1994)

Using an architectural pattern

- Imposes certain characteristics or properties of the software system, such as its structure, its components, its dependencies, etc.),
 - determines structure on a high level of the architecture, thus is typically a central and fundamental design decision.
- The information that "where, how, ..." a well-known architecture / design pattern **is used** is - given software can
- make comparison and maintenance significantly easier,
 - avoid errors.

24/70

Layered Architectures

Example: Layered Architectures

(Calligaris, 2003)

- A layer whose components only interact with components of their **three neighbouring** layers is called protocol-based layer.
- Each layer has its own protocol, which is used by the layers directly above and defines a protocol which is (only) used by the layers directly above.

Example: The ISO/OSI reference model.

26/70

Example: Layered Architectures Cont'd

- Object-oriented layer:** interacts with layers directly (and possibly further) above and below.
- Rules:** the components of a layer may use
 - only** components of a layer directly beneath, or
 - all** components of layers further beneath.

27/70

Example: Layered Architectures Cont'd

- Object-oriented layer:** interacts with layers directly (and possibly further) above and below.
- Rules:** the components of a layer may use
 - only** components of the protocol-based layer directly beneath, or
 - all** components of layers further beneath.

27/70

Example: Three-Tier Architecture

- **presentation layer** (or **gui**): the user interface; presents information obtained from the user; initiates the user's control interaction with the user's logic actions at the logic layer according to user inputs.
- **core system functionality layer**: designed without reference to the presentation layer; may only read/write data according to data layer interface.
- **data layer**: persistent data storage; holds information about how data is organized, read, and written; offers particular chunks of information in a form useful for the logic layer.

Examples: Web-shop, business software (enterprise resource planning), etc.

2870

Layered Architectures: Discussion

- **Advantages:**
 - **protocol-based:** only neighbouring layers are coupled, i.e. components of these layers interact. changes are low data usually encapsulated.
 - **protocol-based distributed** implementation often easy
- **Disadvantages:**
 - performance (as usual) – nowadays often not a problem

29/10

Pipe-Filter

30%

Example: Pipe-Filter

Example: Compiler

Example: UNIX Pipes

```
ls -l | grep Sarch.tex | awk '{ print $5 }'
```

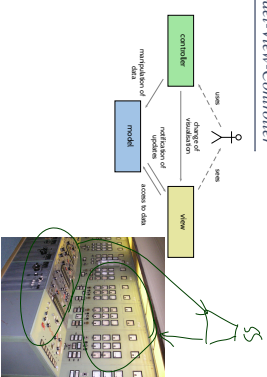

- **Disadvantages**
 - if the filters use a common data exchange format, all filters may need changes if the format is changed, or need to employ (costly) conversions.
 - filters do not use global data, in particular not to handle error conditions.

Design Patterns

Design Patterns

- in a sense the same as architectural patterns, but on a lower scale.
- Often traced back to (Alexander et al., 1977; Alexander, 1979).

Design pattern ... are descriptions of communicating objects and classes that are customized to solve a general problem that can occur in many designs. A design pattern names, abstracts, and describes the key aspects of a common design structure that makes it useful for creating a reusable object-oriented design. (Gamma et al., 1995)

35/70

Example: Pattern Usage and Documentation

Pattern usage in Mockito framework (Mockito, 2017) (Diagram: Ludwig and Lehm, 2013)

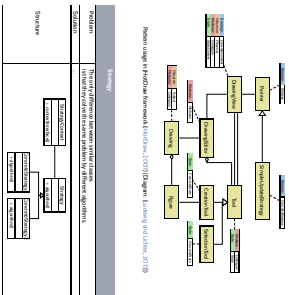

36/70

Example: Strategy

Problem	Solution
<p>Tracing differences between similar objects is that they solve the same problem by different algorithms.</p>	<p>Have one class StrategyContext with all common operations.</p> <p>Another class Strategy provides algorithms for all operations to be performed differently.</p> <p>StrategyContext uses concrete Strategy-objects to resolve the different operations in algorithm.</p>

Example: Pattern Usage and Documentation

Example: Pattern Usage and Documentation

Problem	The behavior of an object depends on its location in the system.
Example	Accessing a resource that is shared by multiple users. The resource is accessed through a shared interface that is used by all users.

Example: Pattern Usage and Documentation

Problem	Changes in the system are complex and difficult to manage. The system is highly complex and difficult to manage.

Other Patterns: Singleton and Memoize

Problem	Of one class, exactly one instance should exist in the system.
Example	Accessing a resource that is shared by multiple users. The resource is accessed through a shared interface that is used by all users.
Problem	The state of an object needs to be preserved in a way that allows to reconstruct the state of the object without having the original object.
Example	Undo mechanism.

- Architecture & Design Patterns
 - allow a **lot** of practice-problem design.
 - promise easier **comprehension** and **maintenance**
- Notable Architecture Patterns
 - Layered Architecture.
 - Model-View-Controller
- Design Patterns read (GALTIMA et al., 1993)
 - Rule-of-thumb:
 - library modules are called from user-code.
 - framework modules call user-code.

Recall:

Definition. Software is a finite description S of a (possibly infinite) set $[S]$ of finite or infinite computation paths of the form $\sigma_0 \xrightarrow{a_0} \sigma_1 \xrightarrow{a_1} \sigma_2 \dots$ where

- $\sigma_i \in \Sigma$, $i \in \mathbb{N}_0$, is called state (or configuration) and
- $a_i \in A$, $i \in \mathbb{N}_0$, is called action (or event)

The (possibly partial) function $[] : S \rightarrow [S]$ is called interpretation of S .

- From now on, we assume that states consist of an input and an output/internal part, i.e. there are Σ_{in} and Σ_{out} such that $\Sigma = \Sigma_{in} \times \Sigma_{out}$.

- Computation paths are then of the form

$$\pi = \left(\begin{pmatrix} \sigma_0^i \\ \sigma_0^o \end{pmatrix} \xrightarrow{a_0} \begin{pmatrix} \sigma_1^i \\ \sigma_1^o \end{pmatrix} \xrightarrow{a_1} \begin{pmatrix} \sigma_2^i \\ \sigma_2^o \end{pmatrix} \dots \right)$$

- We use $\pi \downarrow \Sigma_{in}$ to denote $\pi = \sigma_0^i \xrightarrow{a_0} \sigma_1^i \xrightarrow{a_1} \sigma_2^i \dots$, i.e. the projection of π onto Σ_{in} .

Test Case

Definition. A test case T over Σ and A is a pair (I_n, S_{out}) consisting of

- a description I_n of sets of finite input sequences,
- a description S_{out} of expected outcomes,
- and an interpretation $[]$ of these descriptions

Executing Test Cases

- A computation path
- $$\pi = \left(\begin{pmatrix} \sigma_0^i \\ \sigma_0^o \end{pmatrix} \xrightarrow{a_0} \begin{pmatrix} \sigma_1^i \\ \sigma_1^o \end{pmatrix} \xrightarrow{a_1} \dots \xrightarrow{a_{k-1}} \begin{pmatrix} \sigma_k^i \\ \sigma_k^o \end{pmatrix} \right) \in [I_n]$$
- from $[S]$ is called execution of test case (I_n, S_{out}) if and only if
- there is $k \in \mathbb{N}$ such that $\sigma_0 \xrightarrow{a_0} \dots \xrightarrow{a_{k-1}} \sigma_{k-1} \downarrow \Sigma_{in} \in [I_n]$.
- (A prefix of π corresponds to an input sequence).

Execution π of test case T is called

- **successful** (or **possible**) if and only if $\pi \in [S_{out}]$.
- **injection** an error has been discovered
- **Alternative** test item π **failed to pass the test**
- **Confusing** "test failed"
- **unsuccessful** (or **negative**) if and only if $\pi \in [S_{out}]$.
- **injection** no error has been detected
- **Alternative** test item π **passed the test**
- **Only "yes/no"**

Copyright 2012-2019 by DLR

- A **test suite** is a finite set of test cases (T_1, \dots, T_n) .
- An **execution** of a test suite is a set of computation paths, such that there is at least one execution for each test case.
- An **execution** of a test suite is called **positive** if and only if **at least one** test case execution is **positive**. Otherwise, it is called **negative**.

- Consider the test case
for procedure `ext.in`.
(Empty string has length 0.)
- A tester observes the following software behaviour:
$$\pi = \underbrace{(\pi \mapsto \text{true})}_{\text{true} = 0} \xrightarrow{\pi_1} \underbrace{\pi \mapsto 0}_{\text{program abortion}}$$
- Test execution **positive or negative**?

Note:

- If a tester does not adhere to an allowed input sequence of T , π is **not** a test execution. Thus π is neither positive nor negative (only defined for test executions).
- Same case: power outage (if continuous power supply is considered in input sequence).

Test – (one or multiple execution(s) of a program on a computer with the goal to find errors
([Klostermann and Lohrey, 2013](#))

Not (even) a test (in the sense of this weak definition):

- any **inspection** of the program (no execution).
- **demo** of the program (other goal).
- **analysis** by software-tools for e.g., values of **metrics** (other goal).
- **investigation** of the program with a debugger (other goal).

Systematic Test – a test such that:

- environment conditions are defined or precisely documented.
- inputs have been chosen systematically.
- results are documented and assessed according to criteria that have been fixed before. ([Klostermann and Lohrey, 2013](#))

(Our) Synonyms for non-systematic tests: Experiment, Rumpchecken

In the following **test** means systematic test (if no systematic call it **experiment**)

So Simple?

Strictly speaking, a test case is a tuple $(I_n, \text{Soft}, E_{\text{env}})$ comprising a description E_{env} of (environmental) conditions

E_{env} describes any aspects which **could have an effect** on the outcome of a test execution and cannot be specified as part of I_n , such as:

- Which program version is tested?
 - Built with which compiler, linker, etc.?
 - Test host (OS, architecture, memory size, connected devices (configuration?), etc.)?
 - Which other software (in which version, configuration) is invoked?
 - Who is supposed to test when?
 - etc. etc.
- test executions should be **reproducible and objective** (as possible).

Full reproducibility is hardly possible in practice – obviously (err. why, ...)?

- **Steps towards reproducibility and objectivity:**
- have a fixed build environment.
- use a fixed test host which does not do any other jobs.
- execute test cases **automatically** (test scripts).

The Limits of Software Testing

61/70

Software Examination (in Particular Testing)

- In each examination there are two paths from the specification to results
 - the **development path** (using model, source code, executable, etc.) and
 - the **examination path** (using requirements specifications).
- A check can only discover errors on **exactly one** of the paths.
- If a difference is detected, examination result is **positive**.
- What is not on the path is not checked: crucial: **specification** and **comprehension**.

61/70

62/70

Recall: Quotes On Testing

"Software testing can be used to show the presence of bugs, but never to show their absence"

(E. W. Dijkstra, 1970)

63/70

Why Can't We Show The Absence of Errors (in General)?

Consider a simple pocket calculator for adding 8-digit decimals:

- **Requirement:** if the display shows x , $+$, and y , then after pressing $=$
 - the sum of x and y is displayed if $x + y$ has at most 8 digits,
 - otherwise " E " is displayed.
- With 8 digits both x and y range over $[0, 10^8 - 1]$.

- Thus there are $10^{16} = 10,000,000,000,000,000$ possible input pairs (x, y) to be considered for **exhaustive testing**, i.e. testing every possible case!
- And if we restart the pocket calculator for each test, we **do not know anything** about problems with **sequences** of inputs.. (local variables may not be reinitialized properly, for example.)

64/70

Observation: Software Usually Has Many Inputs

- **Example:** Simple Pocket Calculator.
With ten thousand (10,000) **different** test cases (that's a lot!), 9,999,999,999,990,000 of the 10^{16} possible inputs remain **uncovered**.
In other words:
Only 0.0000000001% of the possible inputs are covered, 99,999,999,999% not touched.

- In diagrams: (red: uncovered, blue: covered)

65/70

- Software is (in general) **not continuous**:
 - Consider a continuous function, e.g. the one to the right:
For sufficiently small ϵ -environments of an input, the outputs **differ only by a small amount**.
 - Physical systems are (to a certain extent) continuous:
For example, if a trucker endures a single car of 9900 kg, we strongly expect the bridge to endure cars of 9910 kg or 9910 kg. And anything of weight smaller than 1000 kg can be expected to be endured.
 - For software, **adjacent inputs may yield arbitrarily distant** output values.
- **Vocabulary**:
 - **Point error**: an isolated input value triggers the error.
 - **Range error**: multiple "neighbouring" inputs trigger the error.
- For software (in general, without extra information) we can **not conclude from some values to others**.
