

# Software Design, Modelling and Analysis in UML

## Lecture 07: Class Diagrams II

2012-11-14

Prof. Dr. Andreas Podelski, Dr. Bernd Westphal  
Albert-Ludwigs-Universität Freiburg, Germany

### Contents & Goals

#### Last Lectures:

- class diagram — except for associations, visibility within OCL type system

#### This Lecture:

- Educational Objectives:** Capabilities for following tasks/questions
  - Please explain this class diagram with associations.
  - Which annotations of an association arrow are semantically relevant?
  - What's a role name? What's it good for?
  - What's "multiplicity"? How did we treat them semantically?
  - What is "reading direction", "navigability", "ownership", "...?"
  - What's the difference between "aggregation" and "composition"?

#### Content:

- Complete visibility
- Study concrete syntax for "associations"
- (Temporarily) extend signature, define mapping from diagram to signature.
- Study effect on OCL
- Where do we put OCL constraints?

2:45

### Casting in the Type System

3:00

### One Possible Extension: Implicit Casts

- We may wish to have

$\vdash 1 \text{ and } \text{false} : \text{Bool}$

(\*)

In other words: We may wish that the type system allows to use 0, 1 : Int instead of true and false without breaking well-typedness.

- Then just have a rule:

$$\frac{A \vdash \text{expr} : \text{Bool}}{\vdash 1 - \text{expr} : \text{Bool}}$$

- With (Cast) (and (Int), and (Bool), and (Fun)), we can derive the sentence (\*), thus conclude well-typedness.

- But:** that's only half of the story — the definition of the interpretation function  $I$  that we have is not prepared, it doesn't tell us what (\*) means...

4:55

### Implicit Casts Cont'd

- So, why isn't there an interpretation for 1 and false?

- First of all, we have (syntax)

$\text{expr}_1 \text{ and } \text{expr}_2 : \text{Bool} \times \text{Bool} \rightarrow \text{Bool}$

- Thus,

$I(\text{and}) : I(\text{Bool}) \times I(\text{Bool}) \rightarrow I(\text{Bool})$

where  $I(\text{Bool}) = \{\text{true}, \text{false}\} \cup \{\perp_{\text{Bool}}\}$

- By definition,

$I[\perp]$  and  $\text{false}[\perp(\alpha, \beta)] = I(\text{and})(I[\perp](\alpha, \beta), I[\text{false}](\alpha, \beta))$ , and there we're stuck.

5:55

### Implicit Casts: Quickfix

- Explicitly define

$$I[\text{and}](\text{expr}_1, \text{expr}_2)[\perp(\alpha, \beta)] := \begin{cases} b_1 \wedge b_2 & , \text{ if } b_1 \neq \perp_{\text{Bool}} \wedge b_2 \neq \perp_{\text{Bool}} \\ \perp_{\text{Bool}} & , \text{ otherwise} \end{cases}$$

where

- $b_1 := \text{toBool}(I[\text{expr}_1](\alpha, \beta))$ ,
- $b_2 := \text{toBool}(I[\text{expr}_2](\alpha, \beta))$ ,

and where

$$\text{toBool} : I(\text{Int}) \cup I(\text{Bool}) \rightarrow I(\text{Bool})$$
  
$$x \mapsto \begin{cases} \text{true} & , \text{ if } x \in \{\text{true}\} \\ \text{false} & , \text{ if } x \in \{\text{false}, 0\} \\ \perp_{\text{Bool}} & , \text{ otherwise} \end{cases}$$

6:00

Bottomline

- There are **wishes** for the type-system which require changes in both, the definition of  $\tau$  and the type system. In most cases not difficult, but tedious.
- **Note:** the extension is still a basic type system.
- **Note:** OCL has a far more elaborate type system which in particular addresses the relation between *Decl* and *Int* (cf. [7]).

Visibility in the Type System

Context

- **Example:** A problem?
- 
- That is, whether an expression involving attributes with visibility is well-typed depends on the class of objects for which it is evaluated.
  - **Therefore:** well-typedness in type environment  $\Delta$  and context  $B \in \mathcal{C}$ :
- $\Delta, B \vdash expr : \tau$   
 $\Delta, B \vdash expr : \tau$   
 $\Delta, B \vdash expr : \tau$
- In particular: prepare to treat "preceder" later (when doing inheritance)

Attribute Access in Context

- If  $expr$  is of type  $\tau$  in a type environment, then it is in **any context**:
- $\Delta \vdash expr : \tau$   
 $\Delta, B \vdash expr : \tau$
- **Accessing attribute  $v$  of a  $C$ -object via logical variable  $w$  is well-typed if**
- $\Delta \vdash w : B$   
 $\Delta, B \vdash v(w) : \tau$   
 $\Delta, B \vdash expr : \tau$
- **Accessing  $C_{0,1}$ - or  $C_{\pm}$ -typed attributes:** similar.

Visibility — The Intuition

Let's study an Example:

Assume  $w_1 : \tau$  and  $w_2 : \tau$  are logical variables. Which of the following syntactically correct (?) OCL expressions shall we consider to be well-typed?

$\xi$ of $x$ :	public	private	protected	not	package
$w_1, n, x = 0$	✓ 1	✗ 1	✗ 1	✗ 1	✗ 1
$w_2, m, x = 0$	✓ 1	✗ 1	✗ 1	✗ 1	✗ 1

Context in Operator Application

**Operator Application:**

$(In_1) \quad \Delta, B \vdash expr_1 : \tau_1, \dots, \Delta, B \vdash expr_n : \tau_n$   
 $\Delta, B \vdash op(expr_1, \dots, expr_n) : \tau$   
 $n \geq 1, w \neq \text{self}(C)$

**Aggregate:**

$(A_1) \quad \Delta, B \vdash expr_1 : \tau_1, \dots, \Delta, B \vdash expr_n : \tau_n$   
 $\Delta, B \vdash op(expr_1, \dots, expr_n) : \tau$   
 $n \geq 1, w = \text{self}(C)$

where  $A = A @ (w_1 + \dots + w_n) @ (w_1 - \dots - w_n)$

```

(ContextBound)
  3, A ← expr : T
  A.D ← expr : T, (r, r.f, expr, p) ∈ set(C)
  (Attr)
  A, B ← v(expr) : T, (r, r.f, expr, p) ∈ set(C)
  A, B ← v(expr) : T, (r, r.f, expr, p) ∈ set(C)
  
```

Example:

$A \leq 0 \wedge B \leq 0 \Rightarrow A \leq 0 \wedge B \leq 0$  (trivial)  
 $A \leq 0 \wedge B \leq 0 \Rightarrow A \leq 0 \wedge B \leq 0$  (trivial)  
 $A \leq 0 \wedge B \leq 0 \Rightarrow A \leq 0 \wedge B \leq 0$  (trivial)  
 $A \leq 0 \wedge B \leq 0 \Rightarrow A \leq 0 \wedge B \leq 0$  (trivial)  
 $A \leq 0 \wedge B \leq 0 \Rightarrow A \leq 0 \wedge B \leq 0$  (trivial)

- **Observation:**
- Whether an expression **does** or **does not** respect visibility is a matter of well-typedness **only**.
- We only evaluate (= apply  $f$ ) to **well-typed** expressions.
- We need **not** adjust the interpretation function  $f$  to support visibility.

Recapitulation

- We extended the type system for
- casts (requires change of  $f$ ) and
- visibility (no change of  $f$ ).
- Later: navigability of associations.

**Good:** well-typedness is decidable for these type systems. That is, we can have automatic tools that check, whether OCL expressions in a model are well-typed.

What is Visibility Good For?

- Visibility is a property of attributes —
- is it useful to consider it in OCL?
- In other words: given the picture above,
- is it useful to state the following invariant (even though  $x$  is private in  $D$ )?

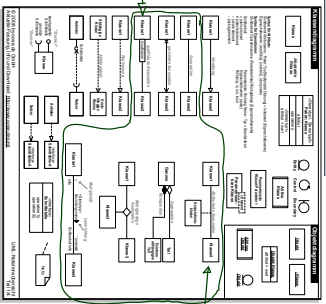

context  $C$  inv :  $n.f > 0$  ?  
 (cf [7], Sect. 12 and 9.2.2)

- **It depends.**
- **Constraints and pre/post conditions:**
- Visibility is sometimes not taken into account. To state “global” requirements, it may be adequate to have a “global view”, i.e. able to look into all objects.
- But: visibility supports “narrow interfaces”, “information hiding”, and similar good design practices. To be more robust against changes, try to state requirements on objects in the terms which are visible to a class.
- Rule of thumb: if classes are separated into requirements on design models, leave them public or provide getters/setters (also).
- **Guards and operation bodies:**
- If in doubt, **yes** (= do take visibility into account).
- Any so-called **action language** typically takes visibility into account.

Associations' Syntax

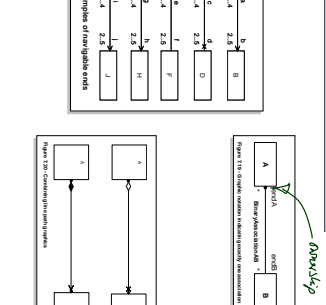

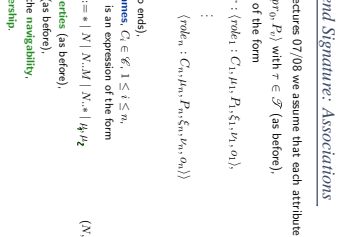

- an association has
    - a name,
    - a reading direction, and of the system
    - at least two ends.
  - Each end has
    - a role name,
    - a multiplicity,
    - a set of properties, such as unique, ordered, etc
    - a qualifier, (or not and how)
    - a visibility,
    - a navigability,
    - and possibly a diamond (weak)
- Warning:** places in the signature to represent the information from the picture.

- **Only** for the course of Lectures 07/08 we assume that each attribute in  $V$ 
    - either is  $(\nu : \tau, \xi, \text{exp}, \alpha, P_1)$  with  $\tau \in \mathcal{D}$  (as before)
    - or is an association of the form
      - $\langle \nu : (\text{role}_1 : C_1, \mu_1, P_1, \xi_1, \nu_1, \alpha_1), \dots \rangle$
      - $\langle \text{role}_n : C_n, \mu_n, P_n, \xi_n, \nu_n, \alpha_n \rangle$
- where
- $n \geq 2$  (at least two ends),
  - $\tau, \text{role}_i$  are just names,  $C_i \in \mathcal{C}$ ,  $1 \leq i \leq n$ ,
  - the multiplicity  $\mu_i$  is an expression of the form  $\mu ::= * | N | N..M | N..* | A; \mu_2$
  - $P_i$  is a set of properties (as before),
  - $\xi_i \in \{+, -, \#, \sim\}$  (as before),
  - $\nu_i \in \{X, \sim, \rightarrow\}$  is the navigability,
  - $\alpha_i \in B$  is the ownership.

- **Only** for the course of Lectures 07/08 we assume that each attribute in  $V$ 
    - either is  $(\nu : \tau, \xi, \text{exp}, \alpha, P_1)$  with  $\tau \in \mathcal{D}$  (as before)
    - or is an association of the form
      - $\langle \nu : (\text{role}_1 : C_1, \mu_1, P_1, \xi_1, \nu_1, \alpha_1), \dots \rangle$
      - $\langle \text{role}_n : C_n, \mu_n, P_n, \xi_n, \nu_n, \alpha_n \rangle$
- and define  $\xi$  and  $N$  as abbreviations, e.g.  $* \# 1 \& \#$
- Alternative syntax for multiplicities:**
- $N..M \& \# \mu ::= N..M | N..* | \mu_1.. \mu_2$  ( $N, M \in \mathbb{N} \cup \{*\}$ )
- Note:  $N$  could abbreviate  $0..N$ ,  $1..N$ , or  $N..N$ . We use last one.
- $\tau, \text{role}_i$  are just names,  $C_i \in \mathcal{C}$ ,  $1 \leq i \leq n$ ,
  - the multiplicity  $\mu_i$  is an expression of the form  $\mu ::= * | N | N..M | N..* | \mu_1.. \mu_2$
  - $P_i$  is a set of properties (as before),
  - $\xi_i \in \{+, -, \#, \sim\}$  (as before),
  - $\nu_i \in \{X, \sim, \rightarrow\}$  is the navigability,
  - $\alpha_i \in B$  is the ownership.

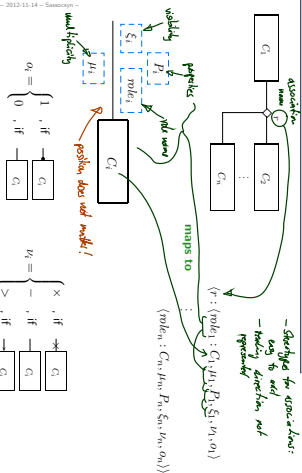

- Also only for the course of 09-109
- we only consider basic type attributes to "belong" to a class (to appear in  $atr(C)$ ).
- associations are not "owned" by a particular class (do not appear in  $atr(C)$ ), but live on their own.

Formally, we only call

$$(\mathcal{S}, \mathcal{E}, V, atr)$$

a signature (extended for associations) if

$$atr : \mathcal{C} \rightarrow 2^{(V \cup \{v\} \cup \mathcal{E})}$$

What If Things Are Missing?

Most components of associations or association end may be omitted for instance [7, 17]. Section 6.4.2, proposes the following rules:

- Name: Use  $A(C_1, \dots, C_n)$  if the name is missing.

What If Things Are Missing?

Various options may be chosen for showing navigation arrows on a diagram. In practice, it is often convenient to suppress some of the arrows and crosses and just show exceptional situations:

- Multiplicity: 1. In my opinion, it's safer to assume 0, 1 or \* if there are no fixed, written, agreed conventions ("respect the worst").
- Properties:  $\emptyset$  (Last: *Simplex!*)
- Visibility: public
- Visibility and Ownership: not so easy. [7, 43]

Signature:

$$s = \{ \{ m_1 \}, \{ \{ C, D \} \}, \{ x : int \}, \dots \}$$

$$\langle x : C, D, m_1, \{ \text{properties} \}, -x, \{ \} \rangle,$$

$$\langle x : D, 0..*, \{ \text{properties} \}, +, \{ \} \rangle,$$

$$\{ \{ C, D \} \} \leftarrow \text{why does type extendable here?}$$

What If Things Are Missing...

... is causing so much trouble (e.g. leading to misunderstanding), why does the standard say "In practice, it is often convenient..."? Is it a good idea to trade convenience for precision/ambiguity?

- Convenience as such is a legitimate goal.
- In UML-As-Sketch mode, precision "doesn't matter", so convenience (for writer) can even be a primary goal.
- In UML-As-Blueprint mode, precision is the primary goal. And misunderstandings are in most cases annoying.

But (even in UML-As-Blueprint mode) If an association in your model have multiplicity  $x_1$  and  $x_2$  (probably) a good idea not to write all these  $x_1$  and  $x_2$ . See the reader about it and leave out the  $x_1$ .
