

Software Design, Modelling and Analysis in UML

Lecture 13: Core State Machines III

2014-12-16

Prof. Dr. Andreas Podelski, **Dr. Bernd Westphal**

Albert-Ludwigs-Universität Freiburg, Germany

– 13 – 2014-12-16 – main –

Contents & Goals

Last Lecture:

- Basic causality model
- Ether

This Lecture:

- **Educational Objectives:** Capabilities for following tasks/questions.
 - What does this State Machine mean? What happens if I inject this event?
 - Can you please model the following behaviour.
 - What is: Signal, Event, Ether, Transformer, Step, RTC.
- **Content:**
 - System configuration
 - Transformer
 - Examples for transformer

– 13 – 2014-12-16 – Prelim –

System Configuration, Ether, Transformer

Ether aka. Event Pool

Definition. Let $\mathcal{S} = (\mathcal{I}, \mathcal{C}, V, atr, \mathcal{E})$ be a signature with signals and \mathcal{D} a structure.

We call a tuple $(Ether, ready, \oplus, \ominus, [\cdot])$ an **ether** over \mathcal{S} and \mathcal{D} if and only if it provides

- a **ready** operation which yields a set of events that are ready for a given object, i.e.

$$ready : Ether \times \mathcal{D}(\mathcal{C}) \rightarrow 2^{\mathcal{D}(\mathcal{E})}$$

- a operation to **insert** an event destined for a given object, i.e.

$$\oplus : Ether \times \mathcal{D}(\mathcal{C}) \times \mathcal{D}(\mathcal{E}) \rightarrow Ether$$

- a operation to **remove** an event, i.e.

$$\ominus : Ether \times \mathcal{D}(\mathcal{E}) \rightarrow Ether$$

- an operation to clear the ether for a given object, i.e.

$$[\cdot] : Ether \times \mathcal{D}(\mathcal{C}) \rightarrow Ether.$$

Ether: Examples

- A (single, global, shared, reliable) FIFO queue is an ether:
 - $Eth = (\mathcal{D}(\mathcal{E}) \times \mathcal{D}(\mathcal{E}))^*$ e.g. $\epsilon = (v, e_1), (v, f_1), (u, e_2)$
the set of all finite sequences of pairs $(u, e) \in \mathcal{D}(\mathcal{E}) \times \mathcal{D}(\mathcal{E})$
 - $ready((u, e).\epsilon, v) = \begin{cases} \{(u, e)\} & \text{if } v = u \\ \emptyset & \text{otherwise} \end{cases}$ $ready(\epsilon, v) = \emptyset$
 - $\oplus(\epsilon, u, e) = \epsilon.(u, e)$
 - $\ominus((u, e).\epsilon, f) = \begin{cases} \epsilon & \text{if } f = e \\ (u, e).\epsilon & \text{otherwise} \end{cases}$ $\ominus(\epsilon, f) = \epsilon$ (empty seq.)
 - $[\cdot]$: remove all (u, e) pairs from a given sequence
- One FIFO queue per active object is an ether.
- Lossy queue (\oplus becomes a relation then).
- One-place buffer.
- Priority queue.
- Multi-queues (one per sender).
- Trivial example: sink, "black hole".
- ...

19/50

15.3.12 StateMachine [OMG, 2007b, 563]

- The order of dequeuing is **not defined**, leaving open the possibility of modeling different priority-based schemes.
- Run-to-completion may be implemented in **various ways**. [...]

Ether and [OMG, 2007b]

The standard distinguishes, e.g., **SignalEvent** [OMG, 2007b, 450], **Reception** [OMG, 2007b, 447].

On **SignalEvents**, it says

A signal event represents the receipt of an asynchronous signal instance. A signal event may, for example, cause a state machine to trigger a transition. [OMG, 2007b, 449] [...]

Semantic Variation Points

The means by which requests are transported to their target depend on the type of requesting action, the target, the properties of the communication medium, and numerous other factors.

In some cases, this is instantaneous and completely reliable while in others it may involve transmission delays of variable duration, loss of requests, reordering, or duplication.

(See also the discussion on page 421.) [OMG, 2007b, 450]

Our **ether** is a general representation of the possible choices.

Often seen minimal requirement: order of sending **by one object** is preserved.

But: we'll later briefly discuss "discarding" of events.

7/60

– 13 – 2014-12-16 – Sether –

Events Are Instances of Signals

Definition. Let \mathcal{D}_0 be a structure of the signature with signals $\mathcal{S}_0 = (\mathcal{T}_0, \mathcal{C}_0, V_0, atr_0, \mathcal{E})$ and let $E \in \mathcal{E}_0$ be a **signal**.

Let $atr(E) = \{v_1, \dots, v_n\}$. We call

$$e = (E, \{v_1 \mapsto d_1, \dots, v_n \mapsto d_n\}),$$

or shorter (if mapping is clear from context)

$$(E, (d_1, \dots, d_n)) \text{ or } (E, \vec{d}),$$

an **event** (or an instance) of signal E (if type-consistent).

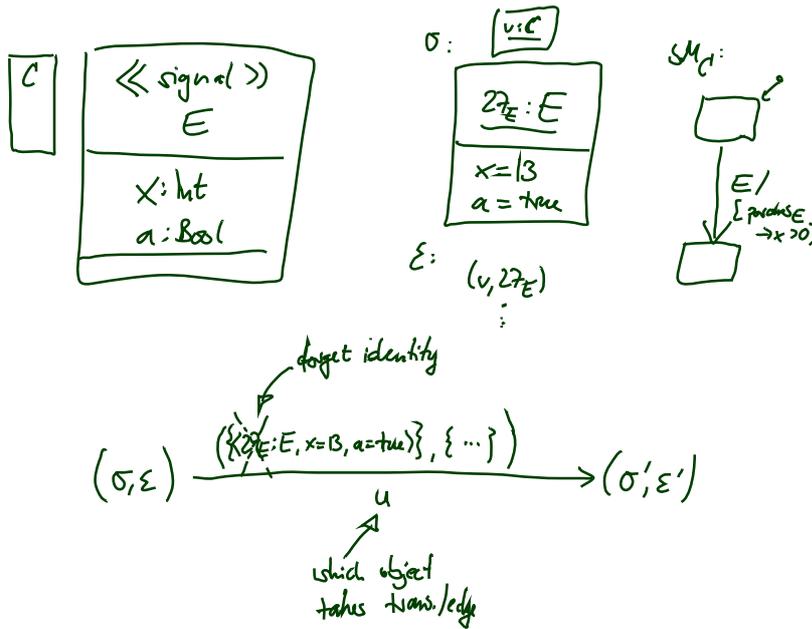

We use $Evs(\mathcal{E}_0, \mathcal{D}_0)$ to denote the set of all events of all signals in \mathcal{S}_0 wrt. \mathcal{D}_0 .

As we always try to maximize confusion...:

- By our existing naming convention, $u \in \mathcal{D}(E)$ is also called **instance** of the (signal) class E in system configuration (σ, ε) if $u \in \text{dom}(\sigma)$.
- The corresponding event is then $(E, \sigma(u))$.

– 13 – 2014-12-16 – Sether –

8/60

Signals? Events...? Ether...?!

The idea is the following:

- **Signals** are **types** (classes).
- **Instances of signals** (in the standard sense) are kept in the **system state** component σ of system configurations (σ, ϵ) .
- **Identities** of signal instances are kept in the **ether**.
- Each signal instance is in particular an **event** — somehow “a recording that this signal occurred” (without caring for its identity)
- The main difference between **signal instance** and **event**:
Events don't have an identity.

- Why is this useful? In particular for **reflective** descriptions of behaviour, we are typically not interested in the identity of a signal instance, but only whether it is an “E” or “F”, and which parameters it carries.

System Configuration

Definition. Let $\mathcal{S}_0 = (\mathcal{T}_0, \mathcal{C}_0, V_0, atr_0, \mathcal{E})$ be a signature with signals, \mathcal{D}_0 a structure of \mathcal{S}_0 , $(Eth, ready, \oplus, \ominus, [\cdot])$ an ether over \mathcal{S}_0 and \mathcal{D}_0 . Furthermore assume there is one core state machine M_C per class $C \in \mathcal{C}$.

A **system configuration** over \mathcal{S}_0 , \mathcal{D}_0 , and Eth is a pair

where

a new type for each class

$(\sigma, \varepsilon) \in \Sigma_{\mathcal{S}} \times Eth$

if Bool & \mathcal{T}_0 then add it and have $\mathcal{D}(Bool) = \mathbb{B}$

- $\mathcal{S} = (\mathcal{T}_0 \dot{\cup} \{S_{M_C} \mid C \in \mathcal{C}\}, \mathcal{C}_0,$
- $V_0 \dot{\cup} \{ \langle stable : Bool, -, true, \emptyset \rangle \}$ *initial state of state machine S_{M_C} of class C*
- $\dot{\cup} \{ \langle st_C : S_{M_C}, +, s_0, \emptyset \rangle \mid C \in \mathcal{C} \}$
- $\dot{\cup} \{ \langle params_E : E_{0,1}, +, \emptyset, \emptyset \rangle \mid E \in \mathcal{E}_0 \},$
- $\{C \mapsto atr_0(C)$
- $\cup \{ stable, st_C \} \cup \{ params_E \mid E \in \mathcal{E}_0 \} \mid C \in \mathcal{C} \}, \mathcal{E}_0)$

set of states of state machine of class C

- $\mathcal{D} = \mathcal{D}_0 \dot{\cup} \{ S_{M_C} \mapsto S(M_C) \mid C \in \mathcal{C} \},$ and \mathcal{E}
- $\sigma(u)(r) \cap \mathcal{D}(\mathcal{E}_0) = \emptyset$ for each $u \in \text{dom}(\sigma)$ and $r \in V_0$. *the only links to sig. instances are via params.*

- 13 - 2014-12-16 - Sstmsconf -

System Configuration: Example

$\mathcal{S}_0 = (\mathcal{T}_0, \mathcal{C}_0, V_0, atr_0, \mathcal{E}), \mathcal{D}_0; \quad (\sigma, \varepsilon) \in \Sigma_{\mathcal{S}} \times Eth$ where

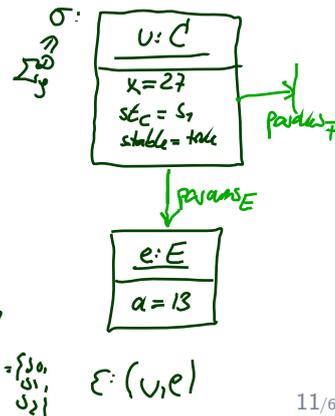

- $\mathcal{S} = (\mathcal{T}_0 \dot{\cup} \{S_{M_C} \mid C \in \mathcal{C}\}, \mathcal{C}_0,$
- $V_0 \dot{\cup} \{ \langle stable : Bool, -, true, \emptyset \rangle \} \dot{\cup} \{ \langle st_C : S_{M_C}, +, s_0, \emptyset \rangle \mid C \in \mathcal{C} \}$
- $\dot{\cup} \{ \langle params_E : E_{0,1}, +, \emptyset, \emptyset \rangle \mid E \in \mathcal{E}_0 \},$
- $\{C \mapsto atr_0(C) \cup \{ stable, st_C \} \cup \{ params_E \mid E \in \mathcal{E}_0 \} \mid C \in \mathcal{C} \}, \mathcal{E}_0)$
- $\mathcal{D} = \mathcal{D}_0 \dot{\cup} \{ S_{M_C} \mapsto S(M_C) \mid C \in \mathcal{C} \},$ and
- $\sigma(u)(r) \cap \mathcal{D}(\mathcal{E}_0) = \emptyset$ for each $u \in \text{dom}(\sigma)$ and $r \in V_0$.

S_{M_C} :

$\mathcal{T}_0 = \{ \text{int}, \{ C, E, F \}, \{ x: \text{int}, a: \text{int}, b: \text{int} \}, \{ C \mapsto \{ x \}, E \mapsto \{ a \}, F \mapsto \{ b \} \}, \{ E, F \} \}$

$\mathcal{T}_1 = \{ \text{int}, Bool \} \cup \{ S_{M_C} \}, \{ C, E, F \}, \{ x, a, b: \text{int} \}, U \{ stable: Bool \}, U \{ st_C: S_{M_C} \}, U \{ params_E: E_{0,1}, params_F: F_{0,1} \}, \{ C \mapsto \{ x \} \cup \{ stable, st_C \} \cup \{ params_E, params_F \}, E \mapsto \{ a \}, F \mapsto \{ b \}, \{ E, F \} \}$

- 13 - 2014-12-16 - Sstmsconf -

System Configuration Step-by-Step

- We start with some signature with signals $\mathcal{S}_0 = (\mathcal{T}_0, \mathcal{C}_0, V_0, atr_0, \mathcal{E})$.
- A **system configuration** is a pair (σ, ε) which comprises a system state σ wrt. \mathcal{S} (not wrt. \mathcal{S}_0).
- Such a **system state** σ wrt. \mathcal{S} provides, for each object $u \in \text{dom}(\sigma)$,
 - values for the **explicit attributes** in V_0 ,
 - values for a number of **implicit attributes**, namely
 - a **stability flag**, i.e. $\sigma(u)(stable)$ is a boolean value,
 - a **current (state machine) state**, i.e. $\sigma(u)(st)$ denotes one of the states of core state machine M_C ,
 - a temporary association to access **event parameters** for each class, i.e. $\sigma(u)(params_E)$ is defined for each $E \in \mathcal{E}$.
- For convenience require: there is **no link to an event** except for $params_E$.

Stability

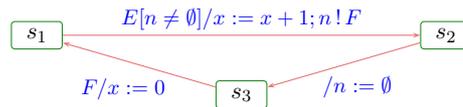

Definition.

Let (σ, ε) be a system configuration over some $\mathcal{S}_0, \mathcal{D}_0, Eth$.

We call an object $u \in \text{dom}(\sigma) \cap \mathcal{D}(\mathcal{C}_0)$ **stable in σ** if and only if

$$\sigma(u)(stable) = true.$$

Where are we?

- **Wanted:** a labelled transition relation

$$(\sigma, \varepsilon) \xrightarrow[u_x]{(cons, Snd)} (\sigma', \varepsilon')$$

on system configuration, labelled with the **consumed** and **sent** events, (σ', ε') being the result (or effect) of **one object** u_x taking a transition of **its** state machine from the current state machine state $\sigma(u_x)(st_C)$.

- **Have:** system configuration (σ, ε) comprising current state machine state and stability flag for each object, and the ether.
- **Plan:**
 - Introduce **transformer** as the semantics of action annotations. **Intuitively**, (σ', ε') is the effect of applying the transformer of the taken transition.
 - Explain how to choose transitions depending on ε and when to stop taking transitions — the **run-to-completion “algorithm”**.

14/60

- 13 - 2014-12-16 - Sstmscrif -

Why Transformers?

- **Recall** the (simplified) syntax of transition annotations:

$$annot ::= [\langle event \rangle ['[' \langle guard \rangle ']'] ['/' \langle action \rangle]]$$

- **Clear:** $\langle event \rangle$ is from \mathcal{E} of the corresponding signature.
- **But:** What are $\langle guard \rangle$ and $\langle action \rangle$?
 - UML can be viewed as being **parameterized** in **expression language** (providing $\langle guard \rangle$) and **action language** (providing $\langle action \rangle$).
 - **Examples:**
 - **Expression Language:**
 - OCL
 - Java, C++, ... expressions
 - ...
 - **Action Language:**
 - UML Action Semantics, “Executable UML”
 - Java, C++, ... statements (plus some event send action)
 - ...

Transformer

not a function, to model non-determinism

Definition.

Let $\Sigma_{\mathcal{C}}$ the set of system configurations over some $\mathcal{S}_0, \mathcal{D}_0, Eth$.

We call a relation *identity of the object which executes the action*

$$t \subseteq \mathcal{D}(\mathcal{C}) \times (\Sigma_{\mathcal{C}} \times Eth) \times (\Sigma_{\mathcal{C}} \times Eth)$$

sys. config. after executing the action

a (system configuration) **transformer**. *system configuration before exec. the action*

- In the following, we assume that each application of a transformer t to some system configuration (σ, ε) for object u_x is associated with a set of **observations**

$$Obs_t[u_x](\sigma, \varepsilon) \in 2^{\mathcal{D}(\mathcal{C}) \times \mathcal{D}(\mathcal{E}) \times Evs(\mathcal{E} \cup \{*, +\}, \mathcal{D}) \times \mathcal{D}(\mathcal{C})}$$

id of sender (pointing to $\mathcal{D}(\mathcal{C})$), *events without identity* (pointing to $\mathcal{D}(\mathcal{E})$), *id of receiver (or destination)* (pointing to $\mathcal{D}(\mathcal{C})$), *id of event* (pointing to Evs), *special symbols for create and destroy* (pointing to $\{*, +\}$)

- An observation $(u_{src}, u_e, (E, \vec{d}), u_{dst}) \in Obs_t[u_x](\sigma, \varepsilon)$ represents the information that, as a "side effect" of u_x executing t , an event (!) (E, \vec{d}) has been sent from u_{src} to u_{dst} .

Special cases: creation/destruction.

Transformers as Abstract Actions!

In the following, we assume that we're **given**

- an **expression language** $Expr$ for guards, and
- an **action language** Act for actions,

and that we're **given**

- a **semantics** for boolean expressions in form of a partial function

$$I[\cdot](\cdot, \cdot) : Expr \rightarrow (\Sigma_{\mathcal{C}} \times \mathcal{D}(\mathcal{C}) \rightarrow \mathbb{B})$$

which evaluates expressions in a given system configuration,

Assuming I to be partial is a way to treat "undefined" during runtime. If I is not defined (for instance because of dangling-reference navigation or division-by-zero), we want to go to a designated "error" system configuration.

- a **transformer** for each action: for each $act \in Act$, we assume to have

$$t_{act} \subseteq \mathcal{D}(\mathcal{C}) \times (\Sigma_{\mathcal{C}} \times Eth) \times (\Sigma_{\mathcal{C}} \times Eth)$$

example:
OCL

$$I[Expr](\sigma, \nu) := \begin{cases} \text{true, if } t_{OCL}(Expr)(\sigma, \{\text{self} \mapsto \nu\}) = \text{true} \\ \text{false, if } t_{OCL}(Expr)(\sigma, \{\text{self} \mapsto \nu\}) = \text{false} \\ \text{undef. otherwise} \end{cases}$$

Expression/Action Language Examples

We can make the assumptions from the previous slide because **instances exist**:

- for OCL, we have the OCL semantics from Lecture 03. Simply remove the pre-images which map to “ \perp ”.
- for Java, the operational semantics of the SWT lecture uniquely defines transformers for sequences of Java statements.

We distinguish the following kinds of transformers:

- **skip**: do nothing — recall: this is the default action
- **send**: modifies ε — interesting, because state machines are built around sending/consuming events
- **create/destroy**: modify domain of σ — not specific to state machines, but let's discuss them here as we're at it
- **update**: modify own or other objects' local state — boring

A Simple Action Language

In the following we use

$$\text{Act}_S := \{ \text{skip} \}$$
$$\cup \{ \text{update}(\text{expr}_1, v, \text{expr}_2) \mid \text{expr}_1, \text{expr}_2 \in \text{OCLExpr}, v \in V \}$$
$$\cup \{ \text{send}(\text{expr}_1, E, \text{expr}_2) \mid \text{expr}_1, \text{expr}_2 \in \text{OCLExpr}, E \in \mathcal{E} \}$$
$$\cup \{ \text{create}(C, \text{expr}_1, v) \mid C \in \mathcal{C} \setminus \mathcal{E}, \text{expr}_1 \in \text{OCLExpr}, v \in V \}$$
$$\cup \{ \text{destroy}(\text{expr}) \mid \text{expr} \in \text{OCLExpr} \}$$

Expr_S : OCL expressions
over S

if (new $C_i \neq \text{NULL}$) ...
 $v := \text{new } C_i$;
if ($v \neq \text{NULL}$) ...

Transformer Examples: Presentation

abstract syntax	concrete syntax
op	
intuitive semantics	...
well-typedness	...
semantics	$((\sigma, \varepsilon), (\sigma', \varepsilon')) \in t_{\text{op}}[u_x] \text{ iff } \dots$ <p style="text-align: center;">or</p> $t_{\text{op}}[u_x](\sigma, \varepsilon) = \{(\sigma', \varepsilon') \mid \text{where } \dots \}$
observables	$Obs_{\text{op}}[u_x] = \{\dots\}$, not a relation, depends on choice
(error) conditions	Not defined if ...

Transformer: Skip

abstract syntax	concrete syntax
skip	<i>skip</i>
intuitive semantics	<i>do nothing</i>
well-typedness	<i>./.</i>
semantics	$t[u_x](\sigma, \varepsilon) = \{(\sigma, \varepsilon)\}$
observables	$Obs_{\text{skip}}[u_x](\sigma, \varepsilon) = \emptyset$
(error) conditions	

Transformer: Update

abstract syntax	concrete syntax
$\text{update}(\text{expr}_1, v, \text{expr}_2)$	$\text{expr}_1.v := \text{expr}_2$
intuitive semantics Update attribute v in the object denoted by expr_1 to the value denoted by expr_2 .	
well-typedness $\text{expr}_1 : \tau_C$ and $v : \tau \in \text{atr}(C)$; $\text{expr}_2 : \tau$; $\text{expr}_1, \text{expr}_2$ obey visibility and navigability	
semantics $t_{\text{update}(\text{expr}_1, v, \text{expr}_2)}[u_x](\sigma, \varepsilon) = \{(\sigma', \varepsilon)\}$ where $\sigma' = \sigma[u \mapsto \sigma(u)[v \mapsto I[\text{expr}_2](\sigma, u_x)]]$ with $u = I[\text{expr}_1](\sigma, u_x)$	
observables $\text{Obs}_{\text{update}(\text{expr}_1, v, \text{expr}_2)}[u_x] = \emptyset$	
(error) conditions Not defined if $I[\text{expr}_1](\sigma, u_x)$ or $I[\text{expr}_2](\sigma, u_x)$ not defined.	

change local state of object u

other does not change
value denoted by expr_2 is σ
object denoted by expr_1 (relative to u_x)
